ROYAL ORSERVATORY, GREENWICH,

London, S.E.

1881, July

SIR,

I have the honor to inform you that the publication & of the Royal Observatory, mentioned on the next leaf, presented to you

by authority of the Lords Commissioners of the Admiralty, have

been forwarded he re with

*I request the favor of an acknowledgment of receipt.

I have the honor to be,

SIR,

Your very obedient Servant,

To Jy Coampbell sque

F & T 1500 12-80

^{*} Non-Compliance with this request will be interpreted as an intimation that similar works are not desired in future.

hidely lodge Rensing tur Lender W July 21. 1881. Recept acknowledge

RESULTS

OF THE

MAGNETICAL AND METEOROLOGICAL OBSERVATIONS

MADE AT

THE ROYAL OBSERVATORY, GREENWICH,

IN THE YEAR

1879 :

UNDER THE DIRECTION OF

SIR GEORGE BIDDELL AIRY, K.C.B. M.A. LL.D. D.C.L.,
ASTRONOMER ROYAL.

PUBLISHED BY ORDER OF THE BOARD OF ADMIRALTY

IN OBEDIENCE TO HER MAJESTY'S COMMAND.

LONDON:

PRINTED BY GEORGE EDWARD EYRE AND WILLIAM SPOTTISWOODE,
PRINTERS TO THE QUEEN'S MOST EXCELLENT MAJESTY.

FOR HER MAJESTY'S STATIONERY OFFICE

1881.

ERRATA.

GREENWICH MAGNETICAL AND METEOROLOGICAL OBSERVATIONS, 1876.

Introduction, page xx, line 13, for quality, read quantity,
page xxix, line 14 from bottom, for later, read earlier.

GREENWICH MAGNETICAL AND METEOROLOGICAL OBSERVATIONS, 1877.

 $\begin{array}{ll} \mbox{Introduction, page xxx, line 14 from bottom, for later, $read$ earlier,} \\ \mbox{,} & \mbox{page liv, line 9 from bottom, for porcelain, $read$ epal glass.} \end{array}$

Page (xxxvi), insert in notes on left-hand page, "The amount of "Sunshine on July 27 was in part estimated, on account of wrong "adjustment of the instrument."

GREENWICH MAGNETICAL AND METEOROLOGICAL OBSERVATIONS, 1878.

Introduction, page xxix, line 15 from bottom, for later, read earlier.

- " page lv, line 24, for porcelain, read opal glass.
- ,, page lxii, line 3, for wires, read silk fibres.
- Page (iii), in title, after MAGNETIC OBSERVATIONS, in.e., (EXCLUDING A DAY OF MAGNETIC DISTURBANCE).
- Page (ii), in the notes at foot of right-hand page, line 5, for Cubic of Air, read Cubic Foot of Air.
- Page (liii), last line in notes on right-hand page, dele " which appears in the following tables."

Astigmatism of the Reflected Pencil of Light, and Use of Cylindrical Lens	
D 000 W. 16621	[a 2]

INTRODUCTION—continued.	PAGI
Image of a Spot of Light formed on the Cylinder	xvi
Photographic Line of Abscissæ: Time-Scale	arii
Photographic Registration of Hour-Lines	vi.
Lower Declination Magnet; and Photographic self-registering Apparatus for	
CONTINUOUS RECORD OF MAGNETIC DECLINATION	xi
Dimensions and Suspension of Lower Declination-Magnet	
Dimensions and Position of the Concave Mirror; its Distance from the Light-Aperture	
and from the Cylinder	a.
Zero and Measure of the Ordinates of the Photographic Curve: New Base-Line	ara
Horizontal-Force-Magnet, and Apparatus for observing it	xx
Dimensions of the Horizontal-Force-Magnet: and its Brick Pier	ax.
Description of the Magnet Carrier and Suspension-Pulleys	x.r.
Planc Mirror and Fixed Telescope for Eye-Observation	x.r
Silk Suspension and Double Box of the Horizontal-Force-Magnet	
Heights above Floor of Brass Pulleys of Suspension-Piece; and of Pulleys of Magnet	
Carrier	xvi.
Distances between the Branches of the Silk Shein at the Upper and Lower Pulleys	xxi.
Oral Copper Damping Bar	xxi.
Position of the Scale and the Telescope for observing the Horizontal-Force-Magnet	a.ri
Observation of the Times of Vibration and of the different Readings of the Scale for	
Different Readings of the Torsion-Circle, and Determination of the Reading of the	
Torsion-Circle and the Time of Vibration when the Magnet is Transverse to the	
Magnetic Meridian	i and win
Computation of the Angle corresponding to One Division of the Scale, and of the	· conce micre
Variation of the Horizontal Force (in Terms of the whole Horizontal Force) which	
moves the Magnet through a Space corresponding to One Division of the Scale	axi
Determination of the Compound Effect of the Vertical Force Magnet and the Declination	· · · · ·
Magnet on the Horizontal-Force-Magnet	xxı
Effect of the Damper	2.22
Determination of the Correction for the Effect of Temperature on the Horizontal-Force-	
Magnet	xxv
Principle adopted for this Determination in 1846 and 1847, and Formula for the Tem-	
perature Correction	xxy
Hot-air Experiments for the Temperature-coefficient made in 1864	xxrii
Experiments for determining the Temperature-coefficient under the actual Circumstances	
of Observation, made in 1868	xxviii
Method of Making the ordinary Eye-Observations	araa
Times of Thermometric Observation for Horizontal-Force-Temperature	exer
Photographic self-registering Apparatus for Continuous Record of Magnetic	
Horizontal Force	xxx
Concave Micror, its Daimeter and Distance from Lamp-aperture	
Part of the Cylinder upon which the Spot of Light for the Horizontal Force Register falls	xxxi
Calculation of the Scale of Harizontal Force on the Photographic Sheet	xxxi
Vertical Force Magnet, and Apparatus for observing it.	23.2
Dimensions, Supports, Currier, and Kniti-edge	asai axrii
Plane Micror and Fixed Telescope for Eye-Observation	xxx ii
Position of the Concave Mirror for Photographic Registration	xxxii
Description of adjustible Serew-weights attached to the Magnet	

NTRODUCTION—continued.	
Rectangular Box, Telescope, and Scale of the Vertical Force Magnet xxxii e	ınd xxxiii
Determination of the Compound Effect of the Declination Magnet, the Horizontal Force	
Magnet, and the Iron affixed to the Electrometer Pole, on the Vertical Force Magnet	xxxiii
Determination of the Times of Vibration of the Vertical Force Magnet in the Vertical	
Plane and in the Horizontal Plane	xxxiii
Computation of the Angle through which the Magnet moves for a Change of One	
Division of the Scale: and Calculation of the Disturbing Force producing a Move-	
ment through One Division, in Terms of the whole Vertical Force	xxxiv
Investigation of the Temperature Correction of the Vertical Force Magnet	xxxiv
Results of Temperature Experiments made in 1868	axxv
Method of making the ordinary Eye-Observations	axxri
Times of Thermometric Observation for Vertical Force Temperature	axari
Photographic self-registering Apparatus for Contineous Record of Magnetic	
Vertical Force	xxxrii
Diameter of Concave Mirror, and Distance from Light-aperture and from Cylinder .	xxxvii
Position of Cylindrical Lens, and support of the Revolving Cylinder	xxxrii
Pencil of Light for Instrumental Base-line Register	xxxvii
Method of computing the Scale for the Ordinates of the Photographic Curve of the Vertical	
Force	xxxvii
Dipping Needles, and Method of observing the Magnetic Dip	axxriii
Description of the Peculiarities of Airy's Instrument	
Illuminating Apparutus, Needles, Zenith Point Needle, and Levels	
Occasional Examinations of the Dip-Instrument and Needles	xli
OBSERVATIONS FOR THE ABSOLUTE MEASURE OF THE HORIZONTAL FORCE OF TERRESTRIAL	
Magnetism	xli
Unifilar Instrument, similar to those used in and issued by the Kew Observatory	xli
Description of the Deflected and Deflecting Magnets	xli
Method of Reduction	xlii
Re-determination of Moment of Inertia of the Deflecting Magnet	xlii
Difference between Results of Old and New Instruments	xlii
Conversion of Results into Metric Measure, and into terms of the C.G.S. unit	xliii
EXPLANATION OF THE TABLES OF RESULTS OF THE MAGNETICAL OBSERVATIONS	xliii
Division of Days of Observation into two Groups: Treatment of the Photographic	.01111
	ii and xliv
The body Day of the second	ana xuv xliv
Results for Horizontal Force and Vertical Force not corrected for Temperature	
	xliv
Indications expressed in terms of Gunss's Magnetic Unit, and Formulæ for Conversion .	xliv
Apparent Diminution of Power of Vertical Force Magnet	xlv
Wires and Photographic self-registering Apparatus for continuous Record of	
Spontaneous Terrestrial Galvanic Currents	xlv
Lengths and Earth-Connexions of the Terrestrial Current Wires	xlvi
Change of route of Wires in 1868, and further change in 1877	xlvi
Galvanometer Needles acted on by the Galvanie Currents	xlvi
Plane Mirrors, Gus-lamp, Pencils of Light, Cylindrical Lenses, and Photographic	
Cylinder for Registration of Galvanic Currents	xlvi
Discussion at the First Series at Records	or Instit

MAGNETICAL AND METEOROLOGICAL OBSERVATIONS.

1879.

GREENWICH MAGNETICAL AND METEOROLOGICAL OBSERVATIONS, 1879.

INTRODUCTION.

§ I. Buildings of the Magnetic Observatory.

In consequence of a representation by the Astronomer Royal, dated 1836, January 12, and a memorial by the Board of Visitors of the Royal Observatory, dated 1836, February 26, addressed to the Lords Commissioners of the Admiralty, an additional space of ground on the south-east side of the former boundary of the Observatory grounds was inclosed from Greenwich Park for the site of a Magnetic Observatory, in the summer of 1837. (This ground was in 1868 extended 100 feet to the south; but no building has been erected on the extension for purposes connected with magnetism or meteorology.) The Magnetic Observatory was erected in the spring of 1838. Its nearest angle in its present form is about 174 feet from the nearest point of the S.E. dome, and about 30 feet from the office of Clerk of Works. It is based on concrete and built of wood, united for the most part by pegs of bamboo; no iron was intentionally admitted in its construction, or in subsequent alterations. Its form, as originally built, was that of a cross with four equal arms, very nearly in the direction of the cardinal magnetic points as they were in 1838; the length within the walls, from the extremity of one arm of the cross to the extremity of the opposite arm, was 40 feet, the breadth of each arm 12 feet. In the spring of 1862, the northern arm was extended 8 feet. The height of the walls inside is 10 feet, and the ceiling of the room is about 2 feet higher. The northern arm of the cross is separated from the central square by a partition, so as to form an ante-room, which is occupied by computers of the Magnetical and Meteorological Department. The meridional magnet for observations of absolute declination, formerly used also for observations of variations of declination, (placed in its position in 1838), is mounted in the southern arm; and the theodolite by which the magnetcollimator is viewed, and by which circumpolar stars for determination of the astronomical meridian are also observed, (for which observation an opening is made in the roof, with proper shutters) is in the southern arm, near the southern boundary of the central square. The bifilar magnet, for variations of horizontal magnetic force u^{-2} P 999.

(crected at the end of 1840), was mounted near the northern wall of the eastern-arm; and the balance-magnetometer, for variations of vertical magnetic force (crected in 1841) was mounted near the northern wall of the western arm. Important changes have subsequently been made in the positions of these instruments, as will be mentioned below. The sidereal-time-clock is in the south arm, near the south-east re-entering angle. The fire-grate (constructed of copper, as far as possible) is near the north end of the west side of the ante-room. Some of these fixtures may contain trifling quantities of iron; and, as the ante-room is used as a computing room, it is impossible to avoid the introduction of iron in small quantities; great care, however, is taken to avoid it as far as possible.

In 1864, a room, called the Magnetic Basement, was excavated below the whole of the Magnetic Observatory except the ante-room; the descent to it is by a staircase close to the south wall of the western arm of the building.

For the theodolite, a brick pier was built from the ground below the floor of the Basement, rising through the ceiling into the south arm of the upper room, and supporting the theodolite in exactly the same position as before.

Instead of a single meridional magnet performing the double functions of "magnet for determining absolute magnetic declination," and "magnet carrying a mirror for photographic register," there are now two meridional magnets, one in the Upper Room and one in the Basement. The upper (original) magnet is in a position about 10 inches north of its former position; it carries a collimator, for observation by the theodolite; but, in reversion of position of the collimator, the collimator is always either above or below the magnet, so that the magnet is always in the same vertical. The lower magnet, procured in the year 1864, is in nearly the same vertical with the upper magnet; it carries the mirror for the photographic register of the continual changes of declination. A massive brick pier is built in the south arm of the Basement, covered by a stone slab; upon it is fixed the gun-metal stand carrying the photographic lamp, and the slit through which it shines; from the stone slab rise three smaller piers, upon which crossed slates are placed; and from these rises a small pier through the ceiling, to the height of 18 inches above the upper floor, carrying the suspension pulleys of the lower magnet; the skein of silk, which supports the lower magnet, passes through a hole in one of the slates. Upon the slates on the brick piers rest the feet of the original wooden stand carrying the suspension of the upper magnet. As, from time to time, the wooden stand has been shifted slightly to the west, with change of the magnetic meridian, its western support had, in course of time, reached such a position that it became necessary in 1876 to place, on the top of the original slate, another slate, bound by brass cramps to the brick pier, but projecting further west. On this the support of the wooden stand now rests.

The bifilar-magnetometer is in the Basement, in a position vertically below its former position. A massive brick pier, surmounted by a thick slab of stone (upon

which the metal stand carrying the photograph lamp and slit is fixed) supports a pier consisting of a back and return-sides, which rises through the ceiling about 2 feet above the upper floor, and is erowned by a slate slab that carries the suspension of the bifilar-magnetometer, and also supports the electrometer.

The vertical-force magnetometer is in the Basement, in a position vertically below its former position; it rests upon a brick pier, capped by a thick stone; to which also is fixed the plate of metal with slit through which passes the light of the photographic lamp.

To the lower part of the theodolite-pier, within the Basement, are fixed telescopes for eye-observation of the bifilar and vertical-force magnetometers. They are protected from accidental violence by guards fixed to the floor, first attached on 1871, May 2.

At the south-east re-entering angle of the Basement (which has been rebated for the purpose) is the horizontal photographic cylinder, which receives the traces of the movements of the declination-magnet and the bifilar-magnet. The angle is so far cut away that the straight line joining their suspensions passes at the distance of one foot from the wall, and thus the cylinder receives the light from the concave mirrors carried by both instruments, at right angles to its surface. The vertical cylinder which receives the traces of the movements of the vertical-force-magnet, and of the self-registering barometer near it, is east of the vertical force pier.

In the south-east corner of the eastern arm is placed the apparatus for self-registration of the spontaneous galvanic currents on the wires leading respectively from Angerstein Wharf to Lady Well Station (on the Mid Kent Railway), and from North Kent Junction (on the Greenwich Railway) to the Morden College end of the Blackheath Tunnel (on the North Kent Railway). The straight lines connecting these points intersect each other nearly at right angles, at a point not far distant from the Observatory (see § 12 below).

The mean-time-clock is on the west wall of the south arm of the Basement.

Adjoining the north wall is the table for photographic operations. Much water is used in these operations, and therefore a pump is provided in the grounds at a distance of about 30 feet from the nearest magnetometer, by which the water is withdrawn from the cistern at the east end of the photographic table and at once discharged into a covered drain. In August of the year 1879, in consequence of changes in the small buildings, the pump was removed to the north-east corner of the north arm of the magnetic building.

Near the west end of the photographic table and fixed to the north wall is the Sidereal Standard Clock of the Astronomical Observatory, Dent 1906, communicating with the Chronograph and other clocks in the Astronomical Department by galvanic wires. It was established in this position at the end of May 1871.

The Basement is warmed by a gas-stove, and ventilated by a large copper tube

nearly two feet in diameter, receiving the flues from the stove and all the lamps, and passing through the upper room to a revolving cowl above the roof. Each of the arms of the basement has a window facing the south, but in general the window-wells are closely stopped.

The variations in the temperature of the instruments have been greatly reduced by their location within this Basement.

A platform, erected above the roof of the Magnetic Building, is used principally for observations of meteors. The sunshine-instrument is placed on a table on this platform.

On the outside of the Magnetic Observatory, near the north-east corner of the ante-room, a pole 79 feet in height is fixed, for the support of the conducting wire to the electrometers; the electrometers formerly planted in the window-seat at the nerth-end of the ante-room have been now removed (see § 23). In 1879, June, the pole was also removed.

The apparatus for naphthalizing the gas used in the photographic registration is mounted in a small detached zinc-built room, erected in 1863, near the west side of the ante-room. The use of the naphthalizing process, which had been discontinued in the years 1865 to 1870, has since 1871 been resumed.

In 1863, a range of seven rooms, usually called the Magnetic Offices, was erected near the southern fence of the grounds, as it existed after the addition made in 1837. Since the summer of 1863, observations of Dip and Deflexion have been made in the westernmost of these rooms, Office No. 7. On 1871, December 1, the Watchman's Clock was moved from the Quadrant Passage of the Astronomical Observatory to Magnetic Office No. 3, and on 1872, November 14, it was again moved from Office No. 3 to No. 1. Offices Nos. 2, 3, and 4 are now used for photographic purposes in connection with the Photoheliograph placed in a dome adjoining Office No. 3 on the south side.

At the distance of 28 feet south (magnetic) from the south-east angle of the southern arm is an open shed about 10° 6° square, supported by four posts at the height of 8 feet, with an adjustible opening at the center of the roof. Under this shed are placed the large dry-bulb and wet-bulb thermometers, with a photographic cylinder, whose axis is vertical, between them; and external to these are the gas flames, whose light passing through the thermometer-tubes above the quicksilver makes photographic traces upon the paper which covers the cylinder.

In October of the year 1879 the "Naylor" Equatoreal was mounted in the ground which had been added in 1868. On account of its proximity to the Magnetic Office No. 7, in which the observations of Dip, and Deflexions of a Magnet for measure of Horizontal Force, are made, it was thought that the iron of the instrument might in some small degree influence these observations. The most delicate test of the existence of any appreciable effect appeared to be the observation

of the time of vibration of the magnet used in the Deflexion experiments. On, however, collecting these observations for some months preceding and following the time of planting the Equatoreal in the position mentioned, no appreciable influence on the observed time of vibration could be detected.

For better understanding of these descriptions, the reader is referred to the Descriptions of Buildings and Grounds with accompanying Maps, attached to the Volumes of Astronomical Observations for the years 1845 and 1862.

§ 2. Upper Declination-Magnet and Apparatus for observing it.

The theodolite, with which the meridional magnet is observed, is by Simms; the radius of its horizontal circle is 8.3 inches: it is divided to 5'; and is read to 5", by three verniers, carried by the revolving frame of the theodolite. The fixed frame stands upon three foot-screws, which rest in brass channels let into the stone pier that stands upon the brick pier rising from the ground of the Magnetic Basement. The revolving frame carries the Y's (with vertical adjustment at one end) for a telescope with transit-axis: the length of the axis is $10\frac{1}{2}$ inches: the length of the telescope 21 inches: the aperture of the object glass 2 inches. The Y's are not carried immediately by the T head which crosses the vertical axis of the revolving frame, but by pieces supported by the ends of that T head, and projecting horizontally from it: the use of this construction is to allow the telescope to be pointed sufficiently high to see à Ursæ Minoris above the pole. The eye-piece of the telescope carries only one fixed horizontal wire, and one vertical wire moved by a micrometerscrew. The opening in the roof of the building permits the observation of circumpolar stars, as high as & Ursæ Minoris above the pole, and as low as & Cephei below the pole.

For supporting the magnet, a braced wooden tripod-stand is provided, whose feet, as above described, rest upon slates covering brick piers in the Magnetic Basement. Upon the cross-bars of the stand rests a double rectangular box (one box completely inclosed within another), both boxes being covered with gilt paper on their exterior and interior sides, and having holes at their north and south ends for illumination of the collimator or reversed telescope carried by the magnet, and for viewing the collimator from the theodolite. The holes in the outer box are covered with glass. On the southern side of the principal upright piece of the stand is a moveable upright bar, turning in the vertical E. and W. plane, upon a pin in its center (which is fixed in the principal upright), and carrying at its top a brass frame supporting two pulleys for suspension of the magnet; this construction is adopted as convenient for giving an E. and W. movement (now very rarely required) to the point of suspension, by giving a motion to the lower end of the bar. The pulleys, whose axes are E. and W., project one on the north side of the moveable

upright, the other on the south side, and are adapted to carry a flat leather strap. Formerly this strap was attached directly to the suspension skein, but at the beginning of the year 1877 this manner of attachment was changed. The end of the strap depending from the north pulley is now connected to a square wooden rod sliding in the corresponding squared hole of a fixed wooden bracket. The suspension skein is attached to the lower end of the wooden rod, so that in raising or lowering the magnet carrier (necessary in some operations) no alteration is made in the free length of the suspension skein. The strap passes from the north pulley over the south pulley, and thence downwards to a small windlass, fixed to the lower part of the moveable upright. The height of the two pulleys above the floor is about 11 ft. 4 in., and the height of the magnet is about 2 ft. 11 in.; the length of the rod, carrying at its upper end the torsion circle, and at its lower end the cradle supporting the magnet, is 1 ft. 4 in.; and the length of strap and rod below the north pulley is about 1 ft. 3 in.; so that the length of the free suspending skein is about 5 feet 10 inches. On 1879, July 10, the cord connecting the leather strap with the small windlass gave way; a new cord was at once attached and the magnet remounted, the same suspension-skein being used.

The magnet was made by Meyerstein, of Göttingen: it is a bar 2 feet long, $1\frac{1}{2}$ inch broad, and about $\frac{1}{4}$ inch thick: it is of hard steel throughout. The magnet-carrier was also made by Meyerstein, but it has since been altered by Simms. The magnet is inserted sideways and fixed by a screw in the double square hook which constitutes the lower part of the magnet-carrier. This lower part turns stiffly on a vertical axis, independently of the upper part, and carries with it the graduated torsion circle: to the upper part is fixed the vernier for reading the circle. The upper part of the magnet-carrier is simply hooked into the skein.

The suspending skein is of silk fibre, in the state in which it is first prepared by silk manufacturers for further operations: namely, when several fibres from the cocoon are united by juxtaposition only (without twist) to form a single thread. The skein is strong enough to support perhaps three times the weight of the magnet, &c.

In the summer and autumn of 1864, an attempt was made to suspend the magnet by a steel wire, capable of supporting the weight 15 lbs.; but the torsion force was found to be so large as greatly to diminish the value of the observations; and the skein was restored on 1865, January 20. (A similar attempt was made for suspension of the lower magnet; the skein, however, was restored on 1865, January 30.)

The upper magnet carries two sliding brass frames, firmly fixed in their places by means of pinching-screws. One of these contains, between two plane glasses, a cross of delicate cobwebs; the other holds a lens of 13 inches focal length and nearly 2 inches aperture. This combination, therefore, serves as a reversed telescope

without a tube: the cross of cobwebs is seen very well with the theodolite-telescope, when the suspension-bar of the magnet is so adjusted as to place the object-glass of the reversed telescope in front of the object-glass of the theodolite, their axes coinciding. The wires are illuminated by a lamp and lens at hight, and by a reflector during the day.

In the original mounting of this magnet the small vibrations were annihilated by a copper oval or "damper," thus constructed: A copper bar, about one inch square, is bent into a long oval form, intended to encircle the magnet (the plane of the oval curve being vertical). A lateral bend is made in the upper half of the oval, to avoid interference with the suspension-piece of the magnet. The effect of this damper is, that after every complete or double vibration of the magnet, the amplitude of the oscillation is reduced in the proportion of 5:2 nearly.

On mounting the photographic magnetometer in the basement, the damper was removed from its place surrounding the upper magnet, and was adjusted to encircle the photographic magnet. The upper magnet remained unchecked in its vibrations till 1866, January 23, when the lower part of its carrier was connected with a horizontal brass bar which vibrates in water.

Observations relating to the permanent Adjustments of the Upper Declination-Magnet and its Theodolite.

1. Determination of the inequality of the pivots of the theodolite-telescope.

1875, August 31. The theodolite was clamped, so that the transit-axis was at right angles to the meridian. The illuminated end of the axis of the telescope was first placed to the East: the level was applied, and its scale was read; the level was then reversed, and its scale was again read; it was then again reversed, and again read, and so on successively six times. The illuminated end of the axis was then placed to the West, and the level was applied and read as before. This process was repeated several times, and the result was, that when the level indicates the axis to be horizontal, the pivot at the illuminated end is really too low by 1".5. Other determinations made 1875, September 21, and 1876, December 1, gave respectively 1".3 and 1".1. The value applied during the year 1879 to the mean level reading is 1 div.3 as before, equivalent to 1".4.

2. Value of one revolution of the micrometer-screw of the theodolite-telescope.

On 1870, December 29, the magnet was made to rest on blocks of wood, and its collimator was used as a fixed mark at an infinite distance. The micrometer of the theodolite-telescope was placed at a definite reading, the telescope was turned until the micrometer-wire bisected the cross, and the circle was then read. The result of several comparisons of circle-readings corresponding to large values of micrometer-reading with circle-readings corresponding to small values of micrometer-reading

was, that one revolution = 1'.34"'2. Similar experiments made 1875, September 1 and December 28, gave respectively 1'.34"'1, and 1'.34"'2. The value used throughout the year 1879 is 1'.34"'2.

3. Determination of the micrometer-reading for the line of collimation of the theodolite-telescope.

1879, January 28. The vertical axis of the theodolite had been adjusted to verticality, and the transit-axis was made horizontal. The declination-magnet was made to rest on blocks, and the cross-wires carried by it were used as a collimator for determining the line of collimation of the telescope of the theodolite. The telescope was reversed after each observation. The mean of 10 double observations was 100° 090. Other observations taken at different times during the year satisfactorily confirmed this value. The value 100° 090 was used throughout the year.

- 4. Determination of the effect of the mean-time-clock on the declination-magnet.
- The observations by which this has been determined are detailed in the volumes for 1840—1841, 1844, and 1845. It appeared that it was necessary to add 9"41 to every reading of the theodolite. The clock was removed to the basement in 1864, having now nearly the same relative position to the lower declination-magnet which formerly it had to the upper. No correction is now applied.
- 5. Determination of the compound effect of the vertical-force-magnet and the horizontal-force-magnet on the declination-magnet.

The details applying to the combined effect of the horizontal-force-magnet and first vertical-force-magnet will be found in the volumes for 1840—1841, 1844, and 1845. It appeared that it was necessary to subtract 55":22 from all readings of the theodolite. In 1848 a new vertical-force-magnet was introduced, and the subtractive quantity was then found to be 42":2. A few experiments made on 1864, May 26, with the horizontal-force-magnet, and an old vertical-force-magnet in the new positions in the basement, seemed to show that the theodolite readings required a subtractive correction of 36":9, but no numerical correction has since been applied. No experiments have been made since mounting the vertical-force-magnet now in use.

 Determination of the error of collimation for the plane glass in front of the outer box of the declination-magnet.

1879, January 28. The magnet was made to rest on blocks. The micrometer head of the telescope was to the east. The plane glass has the word "top" engraved on it, and, in ordinary use, this word is always kept east. The cross-wire carried by the collimator of the magnet was observed with the engraved word alternately east and west. The result of 10 double observations was, that in the ordinary position of the glass 18"5 is to be added to all readings. On 1879, December 9, further

observations gave 19"1. The value 18"8 has been used throughout the year 1879.

7. Determination of the error of collimation of the magnet-collimator, with reference to the magnetic axis of the magnet.

1878, December 10. Observations were made by placing the declination-magnet in its stirrup, with its collimator alternately above and below, and observing the collimator-wire by the theodolite-telescope; the windlass of the suspending skein being so moved that the collimator in each observation was in the line of the theodolite-telescope. The observation was repeated several times. The mean half excess of reading with collimator above (its usual position), over that with collimator below, was 26′. 13″-6. Observations made 1879, December 9, gave 26′. 2″-2. The mean of these values, or 26′. 7″-9, has been used during the year 1879.

8. Effect of the damper.

In the volume for 1840—1841 observations are exhibited showing that the oval copper bar, or damper, which then surrounded what is now the upper declination-magnet, had but little or no effect. Repeated observations, of less formal character, in succeeding years, have confirmed this result. The same bar has encircled the lower declination-magnet since the year 1864. The following observations were made in the year 1865, for ascertaining the effect of the damper on the lower declination-magnet under various circumstances.

On 1865, February 8 and 10, and March 2, the time of vibration of the magnet was observed:—

Mean of times with damper in usual position	23	888
Mean of times with damper reversed end for end	24	.508
Mean of times when damper was removed.	93	.153

These seem to indicate a repulsion of the magnet by the damper, but the magnet came to rest so rapidly that the observations are very uncertain.

On several days from 1865, April 2 to May 12, observations were made for ascertaining the deflection of the magnet produced by turning the damper through a small angle round a vertical axis, passing through its center.

The first series shews clearly that the damper in its usual position drags the magnet; the second shews no certain effect. It seems that the damper possesses two kinds of magnetism, one permanent, the other transiently induced, of nearly equal magnitude; their sum being about Γ_{000} part of the terrestrial effect for the same deflexion.

From 1865, July 25 to August 9, observations were made to ascertain whether the effect of an external deflecting cause is the same with the damper present and the damper removed. The observation was extremely difficult, as the magnet was perpetually in vibration when the damper was removed. A small magnet on the east side of the N. end of the magnetometer, with its north end pointing towards the East (and therefore diminishing the western declination of the magnetometer), was moved to the distance (about five feet) at which it produced a deviation of 5' nearly. The apparent western declination was observed, damper present, and damper removed. It appeared to be less with damper present than with damper removed, by 0', 53'. The separate results are very discordant. If the conclusion has any validity, it tends to show a repulsive power in the damper, opposite to that found in the preceding experiments. This experiment is regarded as inconclusive.

9. Calculation of the constant used throughout the year 1879 in the reduction of the observations of the upper declination-magnet, the micrometer-head of the theodolite-telescope being East.

10. Determination of the time of vibration of the upper declination-magnet under the action of terrestrial magnetism.

On 1873, August 7, this was found to be 31°40; on 1874, December 31, 31°33; on 1875, December 31, 31°25; on 1877, January 10, 31°21; on 1879, January 28, 31°22; and on 1879, December 9, 31°21.

11. Fraction expressing the proportion of the torsion-force to the earth's magnetic force.

By the same process which is described in the Magnetical Observations 1847, but with the system of suspension and silk skein at present in use, the proportion was found, on 1877, January 10, $\frac{1}{155}$; on 1877, December 18, $\frac{1}{155}$; on 1879, January 28, $\frac{1}{155}$; and on 1879, December 9 (after disturbance of the suspension, see page viii), $\frac{1}{175}$.

Determination of the Readings of the Horizontal Circle of the Theodolite corresponding to the Astronomical Meridian.

The reading of the circle corresponding to the astronomical meridian is determined by occasional observation of the stars Polaris and è Ursæ Minoris when near the meridian, either above or below pole. Six measures are usually taken on each night of observation.

The error of level is determined by application of the spirit-level at the time of observation: due regard being paid, in the reduction, to the inequality of pivots already found. One division of the level is considered = 1".0526. The azimuth-reading is then corrected by the quantity:—

Correction = Elevation of W. end of axis \times tan. star's altitude.

The readings of the azimuth circle increase as the instrument is turned from N. to E., S., and W.; from which it follows that (telescope pointing to North), the correction must have the same sign as the elevation of the W. end.

The correction for the azimuth of the star observed has been usually computed independently in every observation, by a peculiar method, of which the principle is fully explained in the volumes for 1840-1841, 1843, 1844, 1845. The formula and table used are the following:—

Let A_{ii} = seconds of arc in star's azimuth, C_s = seconds of time in star's hour-angle,

 a_{μ} = seconds of arc in star's N.P.D. for the day of observation.

Then log. $A_{\alpha} = \log C_s + \log E + \log (a_{\alpha} + F) + \log \cos \diamondsuit$.

The values of log. E, F, and log. cos. \$\dig a, are given in the following table:--

Tabulated Values of Log. Cos. ϕ , for Different Values of C_n and of the Quantities Log. E_n and F_n for the Stars, Polaris and δ Urs. Minoris.

Sometimes, when the star has been observed at larger hour angles, the azimuthal correction has been taken from a manuscript table, having for arguments "Hour Angle" and different values of "North Polar Distance."

Observations for determining the theodolite readings corresponding to the astronomical meridian were made on the following days in 1879:—January 9; March 1; April 11; May 16, 19, 31; June 10, 28; July 26, 29; August 28; September 25; October 1; November 5, 22. As a check on the continued steadiness of the theodolite, observations of a fixed mark (a small hole in a plate of metal above the Observatory Library) have been taken twenty-six times at intervals through the

year. The concluded mean reading for the south astronomical meridian used throughout the year was 27°. 5′. 30″·4.

The following is a description of the method of making and reducing the eyeobservations of the declination-magnet:—

 Λ fine horizontal wire (as stated on page vii) is fixed in the field of view of the theodolite-telescope, and another fine vertical wire is fixed to a wire-plate, moved right and left by a micrometer screw. On looking into the telescope, the diagonally placed cross of the magnetometer is seen, and, during vibration of the magnet, will be observed to pass alternately right and left. The observation is made by turning the micrometer till its wire bisects the image of the magnet-cross at the prearranged times, and reading the micrometer. Then the verniers of the horizontal circle are read.

The mean-time clock is kept very nearly to Greenwich mean time (its error being ascertained each day), and the clock-time for each determination is arranged before hand. Chronometer McCabe 649 has usually been employed for observation.

If the magnet be in a state of disturbance, the first observation is made by the observer applying his eye to the telescope about one minute before the pre-arranged time; he bisects the magnet-cross by the micrometer wire at 45°, and again at 15° before that time, also at 15° and 45° after that time. The intervals of these four observations are the same nearly as the time of vibration of the magnet (page *viii*), and the mean of all the times is the same as the pre-arranged time. The times of observation are usually 1°, 5°, 3°, 5°, 9°, 5°, and 21°, 5° of Greenwich mean time.

The mean of each pair of adjacent readings of the micrometer is taken (giving three means), and the mean of these three is adopted as the result. In practice, this is done by adding the first and fourth readings to the double of the second and third, and dividing the sum by 6.

After removal of the copper damper from the upper to the lower declination-magnet in the year 1864, the upper magnet was usually in a state of vibration; but, since the introduction of the water-damper on 1866, January 23, the number of instances of excessive vibration has been very small. When it appears to be nearly free from vibration, two bisections only of the cross are made, one about 15° before the time recorded, the other about 15° after that time, and the mean adopted as result. (The lower magnet, encircled by the copper damper, never exhibits any troublesome vibrations.)

The adopted result is converted into arc supposing $1^r = 1'.34''\cdot 2$, and the quantity thus deduced is added to the mean of the vernier-readings, to which is applied the constant given in article 9 of the permanent adjustments; the difference between this number and the adopted reading for the Astronomical South Meridian is taken; and thus is deduced the magnetic declination, which is used in determining the zero for the photographic register.

§ 3. General principle of construction of Photographic self-registering Apparatus for continuous Record of Magnetic and other Indications.

The general principle adopted for all the photographic instruments is the same. For the register of each indication, an accurately turned cylinder of ebonite is provided (excepting that for the electrometer, which is of brass). The axis of the cylinder is placed parallel to the direction of the change of indication which is to be registered. If there are two indications whose movements are in the same direction, both may be registered on the same cylinder; thus, the Declination and the Horizontal Force, whose indications of changes of the respective elements travel horizontally, can both be registered upon one cylinder with axis horizontal; the same remark applies to the register of two different galvanic Earth-Currents; the Vertical Force and Barometer can both be registered upon one cylinder with axis vertical; and similarly the Dry-Bulb Thermometer and the Wet-Bulb Thermometer.

To the ends of each ebonite cylinder there are fixed circular brass plates, that which is near the clock-work having a diameter somewhat greater than that of the cylinder. In the further fittings there is a little difference between those for vertical and those for horizontal cylinders. Each horizontal cylinder has a pivot fixed in the brass plate at each end; these revolve each upon two antifriction wheels of the fixed frame. The vertical cylinders have no pivots; there is a perforation through the center of the lower or larger brass plate which, when the cylinder is mounted, is fitted upon a vertical spindle projecting upwards from the center of a second horizontal brass plate; this second brass plate sustains the weight of the vertical cylinder and turns horizontally, being supported by three antifriction wheels (each in a vertical plane) carried by the fixed frame.

Uniform rotatory motion is given to the cylinders by the action of clock or chronometer-work, regulated by either pendulum or duplex-escapement, or chronometer-escapement. For three of the cylinders the axis is placed opposite to the center of the chronometer, and a fork at the end of the hour hand takes hold of a winch fixed to the plate of the cylinder, or (in the vertical cylinders) to the plate that sustains the cylinder. In the cylinder for galvanic earth-currents, and in that of the electrometer, the connection is made by toothed wheels. For the horizontal cylinders, the plane of the chronometer work is vertical; for the vertical cylinders, it is horizontal.

The cylinders employed for the Declination and Horizontal Force registers, for the Vertical Force and Barometer registers, and for the Earth Current registers, are 11½ inches high, and 14¼ inches in circumference; those for the thermometers are 10 inches high, and 19 inches in circumference; that for the electrometer is about 6½ inches high and 19 inches in circumference.

Each cylinder, excepting that of the electrometer, is covered, when in use, by a tube of glass, which is open at one end, and has at the other end a circular plate of ebouite or brass, perforated at its center. The tube is a little larger than the cylinder: its open end is kept in position by a narrow collar of ebouite, and the opposite end by a circular piece of brass fixed to the smaller brass plate at the end of the cylinder.

To prepare the cylinder for register of indications, it is covered with a sheet of sensitised paper; the moisture on the paper usually causes the overlapping ends to adhere with sufficient firmness; the glass tube is then slipped over it, and the cylinder thus prepared is placed (if horizontal) with its pivots in bearing upon its two sets of antifriction wheels, or, (if vertical) with its end-brass-plate upon the rotating brass plate, and its central perforation upon the spindle of that plate; care is taken to ensure connection with the clock-work, and the apparatus is ready for action.

The trace for each instrument is produced by a flame of coal gas charged with the vapour of coal naphtha. For the magnetometers the light shines through a small aperture about 0^m·3 long, and 0^m·01 broad; for the earth-current-apparatus, the barometer, and the electrometer, the aperture is larger. The arrangements for throwing on the photographic paper of the revolving cylinder a spot of light which shall travel in the direction of the cylinder's axis with every motion of either magnetometer or galvanometer, or with the rise and fall of the mercury in the barometer, are as follows.

For each of the three magnetometers, a large concave mirror of speculum metal is carried by a part of the magnet-carrier; although it has a small movement of adjustment relative to the magnet-carrier, yet in practice it is very firmly clamped to it, so that the mirror receives all the angular movements of the magnet. The lamp is placed slightly out of the direction of the straight line drawn from the center of the concave mirror to the center of the cylinder which carries the photographic paper. By the concave mirror, the light diverging from the aperture is made to converge to a place nearly on the surface of the cylinder carrying the photographic paper. The form of the aperture, however, and the astigmatism caused by the inclined reflexion from the mirror, produce this effect, that the image is somewhat elongated and is at the same time slightly curved. To diminish the length there is placed near the cylinder a system of plano-convex cylindrical lenses of glass, with their axes parallel to the axis of the cylinder, and the image is thus reduced to a neat spot of light.

For the registers of galvanic earth-currents, the light, which falls upon a plane mirror carried by each galvanometer, is made to converge to a spot, by a system of cylindrical lenses.

For the barometer, the light, condensed by a vertically placed cylindrical lens, shines through a small horizontal slit in a plate of blackened mica (which moves with the fluctuations of the quicksilver), and thus forms a spot of light.

For the thermometers, the light shines through the vacant part of the tube, and thus forms a line of light.

For the electrometer, the light falling through a slit upon the small mirror carried by the needle support (§ 23), is thence reflected, and, by means of a plano-convex evlindrical lens brought to a small spot.

The spot of light (for the magnets, the earth-currents, the barometer, and the electrometer), or the boundary of the line of light (for the thermometers), moves, with the movements which are to be registered, in the direction of the axis of the cylinder, while the cylinder itself revolves. Consequently, when the paper is unwrapped from the cylinder, there is traced upon it (though not visible till the proper chemical agents have been applied) a curve, of which the abscissa measured in the direction of a line surrounding the cylinder is proportional to the time, while the ordinate measured in the direction parallel to the axis of the cylinder is proportional to the movement which is the subject of measure.

In the instruments for registering the motions of the magnets, the earth-currents, the barometer, and the electrometer, a line of abscisse is actually traced on the paper, by a lamp giving a spot of light in an invariable position, the effect of which on the revolving paper is to trace a line surrounding the cylinder. For the thermometers this is not necessary, as the thermometer-scales are made to earry and to transfer to the photographic paper sufficient indications of the actual reading of the thermometers, by an apparatus which will be described in a following section (§ 16).

Every part of the cylinder apparatus for the magnets, for the earth-currents, and for the electrometer, is covered by cases of blackened zinc or wood, having slits for the moveable spots of light, and holes for the invariable spots; and all parts of the paths of the photographic light are protected as necessary by blackened zinc tubes from the admixture of extraneous light. The cylinder-apparatus for the thermometers is protected in the same manner, the whole, including the stems of the thermometers, and gaslights, being enclosed in a second zinc case, blackened internally.

In all the instruments, the following method is used for attaching, to the sheet of photographic paper, indications of the time when certain parts of the photographic trace were actually made, and for giving the means of laving down a time-scale applicable to every part of the trace. By means of a small moveable plate, arranged expressly for this purpose, the light which makes the trace can at any moment be completely cut off. An assistant, therefore, occasionally cuts off the light (registering in the proper book the clock-time of doing so), and after a few minutes withdraws the plate (again registering the time). The effect of this is to make a visible interruption in the trace, corresponding to registered times. By drawing lines from these points of interruption parallel to the axis of the cylinder, to meet the photographic line of abscissa, or an adopted line of abscissa parallel to it, points are defined upon the line of abscissa corresponding to registered times. The whole length of the exposed part of the paper corresponds to the known time of revolution of the cylinder. A scale being prepared beforehand, whose value for the time of revolution corresponds in length to the circumference of the cylinder, the scale-readings for the registered times of interruption of light are applied to the ordinates corresponding to the interruptions, and the divisions of hours and minutes transferred at once from the scale to the line of abscissae. In practice it is found that the length of the paper is not always the same, and it is necessary, therefore, to use for each instrument several pasteboard scales of different lengths, adapted to various lengths of the photographic sheets.

Since the year 1870, by means of an opening made in the chimneys of the registering lamps of the magnetometers, and in the chimneys of other lamps for the earth current galvanometers, the light at each instrument, when not interrupted, falls directly upon the cylindrical lens in front of the revolving cylinder, and, if allowed to act for a short time, produces, when the sheet is developed, a dark line upon the photographic paper. An apparatus of clock-work, specially arranged by Messrs. E. Dent and Co., acting upon small shutters, uncovers simultaneously the chimney-openings in all the lamps about 25 minutes before each hour, and covers them simultaneously about 21 minutes after each hour. In this way a good series of hour-lines in the direction of the ordinates is formed. By this arrangement increased accuracy of the timeregisters has been obtained, and the labour of the computers much diminished. The system of interrupting the trace by hand is still retained, as giving means of checking the clock indication. No automatic registration of hour-lines has yet been arranged for the Barometer or for the Dry-bulb and Wet-bulb Thermometers. For the electrometer, its driving-clock interrupts the register at each hour as explained in § 23.

§ 4. Lower Declination-Magnet; and Photographic self-registering Apparatus for Continuous Record of Magnetic Declination.

The lower declination-magnet is made by Simms. It is 2 feet long, 1½ inch broad, ¼ inch thick, of hard steel throughout, much harder than the upper declination-magnet.

The magnet-frame consists of an upper piece, whose top is a hook (to be hooked into the suspension-skein), and which carries a concave mirror used for the photographic record in the manner described above. The lower part of this upper piece turns in a graduated horizontal circle, similar to the torsion circle of the upper magnet, and attached to the lower piece or magnet-carrier proper. The lowest part of the carrier is a double square hook, in which the magnet is inserted and is kept in position by the pressure of three screws.

It has been mentioned in § 1 that a small pier, built upon one of the crossed slates which are laid upon three piers rising from below, carries the suspension-pulleys. The suspension-skein rises to one of these pulleys, passes horizontally over a second pulley about 5 inches south of it, and then descends obliquely to a windlass which is fixed to the stone slab about 2 ft, 3 in, south of the center of the magnet.

The height of the pulley above the floor of the Basement is $10 \text{ ft. } 4\frac{3}{4} \text{ in.}$ As the height of the magnet above the floor is $2 \text{ ft. } 10\frac{1}{2} \text{ in.}$, and the length of the magnet frame is 1 ft. 3 in., there remains $6 \text{ ft. } 3\frac{1}{4} \text{ in.}$ of free suspending skein. On 1879, June 7, the suspension-skein gave way. The defective part, near one end, being removed, the magnet was, on June 9, again suspended by the same skein.

One of the revolving cylinders (§ 3) is used for the photographic record of the Declination-Magnet and the Horizontal-Force-Magnet. In the preparation of the basement in 1864, as has been stated, the south-eastern re-entering angle was cut away, so that the straight line from the suspending skein of the declination-magnet to the center of those of the bifilar magnet passes through a clear space, in which the registering apparatus is placed.

The concave mirror of the declination-magnet is 5 inches in diameter, and is above the top of the magnet-box. The distance of the light aperture from the mirror is about 25.3 inches. The bright spot formed by the reflection of light from the mirror is received on the south side of the cylinder, near its west end.

For the declination-magnet, the values, in minutes and seconds of arc. of movements of the photographic spot in the direction of the ordinate, are thus deduced from a geometrical calculation founded on the measures of different parts of the apparatus. The distance of the cylinder from the concave mirror is 132·11 inches, and a movement of 1 of the mirror produces a movement of 2 in the reflected ray. From this it is found that I of movement of the mirror is represented by 4.611 inches upon the photographic paper. A small scale of paste-board is prepared, (for which a glass scale is in some operations substituted.) whose graduations correspond in value to minutes and seconds so calculated. The zero of the ordinatescale is found in the following manner. The time-scale having been laid down as is already described, and actual observations of the position of the upper declinationmagnet having been made with the eye and the telescope (as has been fully described at page xr) at certain registered times, there is no difficulty (by means of these registered times) in defining the points of the photographic trace which correspond to the observed positions. The pasteboard scale being applied as an ordinate to one of these points, and being slid up and down till the scale reading which represents the reading actually taken by the eye-observation falls on that point, the reading of the scale where it crosses the line of abscissæ is immediately found. This process rests on the assumption that the movements of the upper and lower magnets are exactly similar. The various readings given by different

observations, so long as there is no instrumental change, will scarcely differ, and may be combined in groups, and thus an adopted reading for the line of abscissæ may be obtained. From this, with the assistance of the same pasteboard scale, there can then be laid down without difficulty a new line, parallel to the line of abscissæ, whose ordinate would represent some whole number of degrees, or other convenient quantity.

§ 5. Horizontal-Force-Magnet and Apparatus for observing it.

The horizontal-force-magnet, furnished by Meyerstein of Göttingen, is, like the two declination-magnets, 2 feet long, $1\frac{1}{2}$ inch broad, and about $\frac{1}{4}$ inch thick. For its support (as is mentioned at page iv), a brick pier in the eastern arm of the Magnetic Observatory, built on the ground below the basement floor, rises through the floor of the upper room, and carries a slate slab, to the top of which a brass frame is attached, earrying two brass pulleys (with their axes in the same east and west line) in front of the pier, and two (in a similar position) at the back of the pier; these constitute the upper suspension-piece. A small windlass is attached to the back of the pier at a convenient height. The magnet-carrier consists of two parts. The upper part is a horizontal bar, $2\frac{1}{2}$ inches long, whose ends are furnished with verniers for reading the graduations of the torsion-circle (a portion of the lower part, to be mentioned below). On the upper side of this horizontal bar are two small pulleys with axes horizontal and at right angles to the vertical plane passing through the length of the bar: by these pulleys the apparatus is suspended, as will be mentioned. From the lower side of the horizontal bar, a vertical axis projects downwards through the center of the torsion-circle, in which it turns by stiff friction. The lower part of the magnet-carrier consists, first of the torsion-circle, a graduated circle about 3 inches in diameter: next, immediately below the central part of the torsion-circle. is attached (but not firmly fixed) a circular piece of metal from which projects downwards a frame that, by means of three gramps and screws, earries the photographic coneave mirror, with the plane of its front under the center of the vertical axis: this circular piece of metal has a radial arm upon which acts a screw carried by the torsion-circle, for giving to the concave mirror small changes of azimuthal position. Thirdly, there is fixed to the torsion-circle, at the back of the mirror-frame but not touching it, a bar projecting downwards, bent horizontally under the mirror-frame and then again bent downwards, carrying the cramps in which the magnet rests; and, still lower, a small plane mirror, to which a fixed telescope is directed for observing by reflexion the graduations of a fixed scale (to be mentioned shortly). Under the two small pulleys mentioned above passes a skein of silk; its two branches rise up and pass over the front pulleys of the suspension-piece, then over its back pulleys, and then descend and pass under a single large pulley, whose axis is attached to a

wire that passes down to the windlass. Supported by the two branches of the skein, the magnet swings freely, but the direction that it takes will depend on the angular position of its stirrup with respect to the upper horizontal bar; it is intended that the index should be brought to such a position on the torsion-circle that the two suspending branches should not hang in one plane, but should be so twisted that their torsion-force will maintain the magnet in a direction very nearly E. and W. magnetic (its marked end being W.): in which state an increase of the earth's magnetic force draws the marked end towards the N., till the torsion-force is sufficiently increased to resist it; or a diminution allows the torsion-force to draw it towards the S. The magnet, with its plane mirror, hangs within a double rectangular box (one box completely inclosed within another) covered with gilt paper, similar to that used for the declination-magnet; in its south side there is one long hole, covered with glass, through which the rays of light from the scale enter to fall on the plane mirror, and the rays reflected by the mirror pass to the fixed telescope. The vertical rod (below the torsion-circle), which carries the magnet-stirrup, passes through a hole in the top of the box. Above the magnet box is the concave mirror above mentioned. The height of the brass pulleys of the suspension-piece above the floor is 11th 8th 5; that of the pulleys of the magnet-carrier is 4th 2^m·5; and that of the center of the plane mirror is about 3^{ft.} 1^{in.}. The distance between the branches of the silk skein, where they pass over the upper pulleys, is 1 in. 14; at the lower pulleys the distance between them is $0^{\text{in}} \cdot 80$.

An oval copper bar (exactly similar to that for the declination-magnet), embraces the magnet, for the purpose of diminishing its vibrations.

The scale, which is observed by means of the plane mirror, is in a horizontal position, and is fixed to the South wall of the East arm of the Magnetic Basement. Till 1879, December 22, the scale was of pasteboard; on this day a new opal glass scale by Negretti and Zambra was substituted. The numbers of the scale increase from East to West, so that when the magnet is inserted in the magnet-cell with its marked end towards the West, increasing readings of the scale (as seen with a fixed telescope directed to the mirror which the magnet carries) denote an increasing horizontal force. A normal to the scale from the center of the plane-mirror meets the scale at the division 51 nearly; the distance from the center of the plane-mirror to division 51 of the scale is 90% inches.

The telescope is fixed on the east side of the brick pier which supports the stone pier of the declination-theodolite in the upper observing room. The angle between the normal to the scale (which coincides nearly with the normal to the axis of the magnet) and the axis of the telescope, is about 38°, and the plane of the mirror is therefore inclined to the axis of the magnet about 19°.

Observations relating to the permanent Adjustments of the Horizontal-Force-Magnet.

1. Determination of the times of vibration and of the different readings of the scale for different readings of the torsion-circle, and of the reading of the torsion-circle and the time of vibration when the magnet is transverse to the magnetic meridian.

To render the process intelligible, it may be convenient to premise the following explanation.

Suppose that the magnet is suspended in its stirrup which is firmly connected with the small plane mirror, with its marked end in a magnetic westerly direction (not exactly west, but in any westerly direction between north and south), and suppose that, by means of the telescope directed towards that mirror, the scale is read, or (which is the same thing) the position of the plane mirror and of the stirrup, and therefore that of the axis of the magnet, is defined. Now let the magnet be taken out of the stirrup and replaced with its marked end easterly. The terrestrial magnetic power will now act as regards torsion, in the direction opposite to that in which it acted before, and the magnet will therefore take up a different position. But by turning the torsion-circle, which changes the amount and direction of the torsion-power produced by the oblique tension of the suspending cords, the magnet may be made to take the same position, but with reversed direction of poles, as at first (which will be proved by the reading of the scale, as viewed in the plane mirror, being the same). The reading of the torsion-circle will now be different from what it was at first. The effect of this operation then is, to give us the difference of torsion-circle-readings for the same position of the magnet-axis with the marked end opposite ways, but it gives no information as to whether the magnetaxis is accurately transverse to the meridian, inasmuch as the same operation can be performed whether the magnet-axis is transverse or not.

But there is another observation which will inform us whether the magnet-axis is or is not accurately transverse. Let the time of vibration be taken in each position of the magnet. Resolve the terrestrial magnetic force acting on the poles of the magnet into two parts, one transverse to the magnet, the other longitudinal. In the two positions of the magnet (marked end westerly and marked end easterly, with axis in the same position), the magnitude of the transversal force is the same, and the changes which the torsion undergoes in a vibration of given extent are the same, and the time of vibration (if there were no other force) would be the same. But there is another force, namely, the longitudinal force; and when the marked end is northerly, this tends from the center of the magnet's length, and when it is southerly it tends towards the center of the magnet's length; and in a vibration of given extent this produces force, in one case increasing that due to the torsion and in the

other case diminishing it. The times of vibration therefore will be different. is only one exception to this, which is when the magnet-axis is transverse to the magnetic meridian, in which case the longitudinal force vanishes.

The criterion then of the position truly transverse to the meridian (which position is necessary in order that the indications of our instrument may apply truly to changes of the magnitude of terrestrial magnetic force without regard to changes of direction) is this. Find the readings of the torsion-circle which, with magnet in reversed positions, will give the same readings of the scale as viewed by reflexion in the plane mirror, and will also give the same time of vibration for the magnet. With these readings of the torsion-circle the magnet is transverse to the meridian: and the difference of the readings of the torsion-circle is the difference between the position when terrestrial magnetism acting on the magnet twists it one way, and the position when the same force twists it the opposite way, and is therefore double the angle due to the torsion-force of the suspending lines when they neutralize the force of terrestrial magnetism.

On 1879, January 2, some frayed parts of the suspension-skein were removed. The magnet was then remounted, and the following observations made: -

	The Marked end of the Magnet,										
1879.	West.					East.					
Day,	Circle for 1 of of		the Times	Torsion- Scale Scale Readings the			Mean of the Times of Vibration				
	0	rttv.	div	6	0	div	civ-	5			
Jan. 2	145 146 147	41.82 49.75 58.12	7:93 8:37	20.72	228 229 230	43°44 52°15 54°65	8:72 7:49	20.95 20.85			

The times of vibration and scale readings were sensibly the same, when the torsion-circle read 146°, 18', marked end West, and 229°, 0', marked end East, differmg 82', 42'. Half this difference, or 41', 21', is the angle of torsion when the magnet is transverse to the meridian. The value deduced from the whole of the observations above was 41°, 23°2. On 1879, June 7, the cord sustaining the suspension-skein gave way. A new cord was attached on June 9, and the magnet remounted. On July 17 another set of observations for determination of the angle of torsion gave 41, 20'0, and a further set made on 1880, January 2, gave 41', 22'0,

The value adopted in the reduction of observations throughout the year 1879 was 41 . 22'·0.

d

The reading adopted for the torsion-circle, marked end of magnet west, was 146°, 0' throughout the year.

2. Computation of the angle corresponding to one division of the scale, and of the variation of the horizontal force (in terms of the whole horizontal force) which moves the magnet through a space corresponding to one division of the scale.

It was found by accurate measurements, on 1864, November 3, that the distance from 51^{dis.} on the scale to the center of the face of the plane mirror is 90°838 inches, and that the length of 30^{div.}85 of the scale is exactly 12 inches; consequently the angle at the mirror subtended by one division of the scale is 14′.43″.25, or, for change of one division of scale-reading, the magnet is turned through an arc of 7′.21″.625.

The variation of horizontal force (in terms of the whole horizontal force) for a disturbance through one division of the scale, is computed by the formula, "Cotan, angle of torsion × value of one division in terms of radius." Using the numbers above given, the value is found to be 0.002431, which has been used throughout the year 1879.

3. Determination of the compound effect of the vertical-force-magnet and the declination-magnet on the horizontal-force-magnet, when suspended with its marked end towards the West.

The details of the experiments, made while the old vertical-force-magnet was in use, will be found in the several volumes for 1840—1841, 1844, and 1845. The effect was to increase the readings by 0^{div.}487. On mounting a new vertical-force-magnet in 1848, similar experiments were made, and the resulting number was 0^{div.}45. These quantities are totally unimportant in their influence on the registers of changes of horizontal force. No experiments have been made since the magnets were placed in the basement.

4. Effect of the damper.

In the year 1865, from May 17 to May 25, observations were made for ascertaining the deflection of the magnet produced by turning the damper through a small angle round a vertical axis passing through its center.

Greenwich Magnetical and Meteorological Observations, 1879.

On 1865, July 25, observations were made to ascertain whether the effect of an external deflecting cause is the same with the damper present and the damper removed. A small magnet was placed with its marked end pointing north at the distance 4 feet south of the unmarked end of the horizontal-force-magnet, deflecting the magnet through 1^{div.} of the scale, and the scale-readings were observed with the damper in its usual place and with the damper away. Three experiments were made, containing twenty-four observations of position. Not the smallest difference of position of the horizontal-force-magnet was produced by the presence or absence of the damper. The observations were very easy, and the result is certain.

No experiments on the damper have been made since 1865.

5. Determination of the correction for the effect of temperature on the horizontal-force-magnet.

In the Introduction to the volume of Magnetical and Meteorological Observations for 1547 will be found a detailed account of observations made in the years 1846 and 1847 for determination of this element. The principle adopted was that of observing the deflection which the magnet (to be tried) produces on another magnet; the magnet (to be tried) being carried by the same frame which carries the telescope that is directed to the plane mirror attached to the other magnet, and which also carries the scale that is viewed in these experiments by reflection in that plane mirror. The rotation of the frame was measured by a graduated circle about 23 inches in diameter. The magnet (to be tried) was always on the eastern side of the other magnet. It was enclosed in a copper trough, which was filled with water at different temperatures. One end of the magnet (to be tried) was directed towards the other magnet. The values found for correction of the results as to horizontal force determined with the magnet at temperature t^c in order to reduce them to what they would have been if the temperature of the magnet had been 32^c , expressed as multiples of the whole horizontal force, were,

When the marked end of the magnet (to be tried) was West.

$$0.00007137 (t - 32) + 0.000000898 (t - 32)^2$$
.

When the marked end of the magnet (to be tried) was East.

$$0.00009050 (t - 32) + 0.000000626 (t - 32)^{2}$$

The mean, or

$$0.0000 \times 0.093 \ (t = 32) + 0.0000000762 \ (t = 32)^2$$

has been embodied in tables which have been used in the computation of the "Reduction of Magnetic Observations 1848–1857," attached to the volume of Observations for 1859, and in the computation for "Days of Great Magnetic Disturbance 1841–1857," attached to the volume for 1862. The same formula has been employed

^{*} By inadvertence in printing the Introduction, 1847, the letter t has been used in two different senses, as commencing from 0° and as commencing from 32°.

in the "Reduction of the Magnetic Observations, 1858-1863," published in the volume for 1867.

In the year 1864 observations were made for ascertaining the temperature-coefficient by heating the magnet by hot air. The magnet, whose variation of power in different temperatures was to be determined, was placed in a copper box planted upon the top of a copper gas stove, whose heat could be regulated by manipulation of a tap, and from which rose a stream of heated air (not the air vitiated by combustion) through a large opening in the bottom of the box. The stove used for this purpose was the same which is now used for warming the Magnetic Basement. It was placed in the Magnetic Office, No. 7, in a position south magnetic of the deflexion-The hot air which rose through the opening in the center of the bottom was discharged by adjustible openings near the extreme ends of the top. Three windows were provided for reading three thermometers. The box, and the magnet which it inclosed, were placed in a magnetic E. and W. position. The needle whose deflection exhibited the power of the magnet was that which is employed in the ordinary use of the deflexion-apparatus. The proportion of the power of the magnet (under definite circumstances) to the earth's directive horizontal power was expressed by the tangent of the angle of deviation. Observations were made with temperatures both ascending and descending. The intervals of observation at different temperatures were sufficiently small to permit the assumption that the earth's force had not sensibly changed. The following is an abstract of the principal results:-

Omitting some days of less perfect series, satisfactory series of observations were made on 1864, February 21, 22, 23, and March 10. The tangents of angle of deflection were as follows:

13 obser 13	vations wi	th marked end E	ean tempera	ıture 36°8 Fali	renheit g	ave 0·403711
21 25	.,	marked end E }	,,	61.3	,,	0.400836
17 16	.,	$ \begin{array}{c} \operatorname{marked\ end\ E} \\ \text{,,} & \end{array} $,,	90.3	,,	0.400579

From these it was inferred that the tangent of angle of deflection could be represented by—

0.404559 ×
$$\left\{1 - 0.0004610 \times (t - 32) + 0.000005061 \times (t - 32)^2\right\}$$

On comparing the quantity within the bracket (which expresses the law of magnetic power as depending on temperature) with that found in 1847, which, as above stated, is—

$$\left\{1 - 0.00008093 \times (t - 32) - 0.000000762 \times (t - 32)^2\right\}$$
 d 2

it will be seen that the difference is great. The second terms differ greatly in magnitude, and the third terms in sign.

Possibly some light may be thrown on the difference by the following remark. The two formulæ give the same values for $t=32^{\circ}$ and for $t=97^{\circ}$. And they give equal degrees of change per degree when $t=65^{\circ}$. It would seem therefore that the real discordance is in the experimental values for the mean temperatures only, or principally; and that it is probable that there is some error in the hot-air process for the middle temperatures.

The results of a similar examination of the Old Vertical Force Magnet, which was in use from 1848 to the beginning of 1864, are here inserted, although not applying to the observations of the present volume. Omitting less perfect series, observations made on 1864, February 21 and 24, gave the following values for tangents of angles of deflection:—

7	bservations with	marked end E {			0		
7	,,	,. W ∫	at mean	temper	rature 34 [°] 2 Fal	arenheit g	ave 0·279985
9	,,	marked end E \			57:0		0.275111
11	,,	" W∫		"	51.0	**	0.249111
7	**	marked end E \			00.		0.050550
7	,,	., W ʃ		٠,	86.5	"	0.270778

From these it was inferred that the tangent of angle of deflection could be represented by—

$$0.280526 \, \times \left\{1\, - 0.00088607 \, \times (t\, - 32) \, + 0.0000045594 \, \times (t\, - 32)^2\right\}$$

The expression found in 1847 for the law of force in the original Vertical Force Magnet was—

$$\left\{1\,-\,0.00015816\,\times(\ell\,-\,32)\,-\,0.000001172\,\times(\ell\,-\,32)^2\right\}$$

giving a discordance of the same kind as that found for the horizontal force, but still larger. The formulæ agree only when $t = 32^{\circ}$ and when $t = 159^{\circ}0$. The discordance cannot be removed by a supposition similar to that made above.

Returning now to the temperature-correction of the Horizontal Force Magnet. The unsatisfactory character of the comparisons just given made it desirable at the beginning of 1868 to try the method of heating the air of the Magnetic Basement generally (by means of the gas-stove), leaving the magnets in all respects in their ordinary state, and comparing their indications as recorded in the ordinary way, but at different temperatures. Experiments were at first made at intervals of a few hours in the course of one day, but it was soon found that the magnet did not acquire the proper temperature; moreover, the result was evidently affected by

[•] This method was first used for magnets, so far as I am aware, at the Kew Observatory. It had been used for pendulums by General Sir Edward Sabine and by myself.

diurnal inequality. After this, an entire day was in each case devoted to the effects of each temperature (high or low, as the case might be). The principal series of observations were made with the horizontal force magnet in its ordinary position, or marked end to the west; but a few were made with the marked end to the east. In some instances, the numbers given are the result each of several observations; but in other instances, the result is that of a single observation, taken when all the apparatus had acquired unusual steadiness. The following are the results:—

These results do not differ greatly from those which are given by application of the formula found in 1847. It is important to observe that they include the entire effects of temperature upon all the various parts of the mounting of the magnet, as well as on the magnet itself; and for this reason appear to be deserving of great confidence. Still it seemed prudent, at present, to omit application of corrections for temperature.

The method of observing with the horizontal-force-magnet is the following:—

A fine vertical wire is fixed in the field of view of the telescope, which is directed to the plane mirror carried by the magnet. On looking into the telescope, the graduations of the fixed scale, mentioned in page arii, are seen; and during the oscillations of the magnet, the divisions of the scale are seen to pass alternately right and left across the wire. The clock-time, for which the position of the magnet is to be determined, is 5 minutes earlier than that for the observation of declination. The first observation is made by the observer applying his eye to the telescope 40° (or about two vibrations) before the arranged time, and, if the magnet is in a state of vibration, he observes the next four extreme points of vibration on the scale, and the mean of these is adopted in the same manner as for the declination-observations; but if it appears to be at rest, then at 10° before the pre-arranged time, he notes the reading of the scale; and 10° after the pre-arranged time he notes whether the reading continues the same, and if it does, that reading is adopted as the result. If there is a slight difference in the readings, the mean is taken. The times of observation are usually 1°, 3°, 9°, and 21° of Greenwich mean time.

The number of instances when the magnet was observed in a state of vibration during the year 1879 is very small.

A thermometer, the stem and bulb of which reach considerably below the attached scale, is so planted in a nearly upright position on the outer magnet box, that the bulb projects into the interior of the inner box, that actually contains the magnet. Readings of this thermometer are taken on every week day, at 0^h, 1^h, 2^h, 3^h, 9^h, 21^h, 22^h, and 23^h. Its index error is insignificant. A few readings are taken on Sunday. Self-registering maximum and minimum thermometers placed outside the box were formerly read twice every day, but in consequence of the very small diurnal range of temperature, these observations have not been continued.

§ 6. Photographic self-registering Apparatus for Continuous Record of Magnetic Horizontal Force.

Referring to the general description of photographic apparatus, the following remarks apply more particularly to that which is attached to the horizontal-force-magnet. A concave mirror of speculum-metal, 4 inches in diameter, is carried by the magnet-carrier. The light of a gas-lamp shines through a small aperture about 0ⁱⁿ⁻³ high, and 0ⁱⁿ⁻⁰01 broad (which is supported by the solid base of the brick pier carrying the magnet-support), at the distance of about 21·25 inches from the concave mirror, and is made to converge to a point, on the north surface and near the east end of the same revolving cylinder which receives the light from the concave mirror of the declination-magnet. A cylindrical lens parallel to the axis of the cylinder receives the somewhat elongated image of the source of light, and converts it into a well-defined spot. The motions of this spot parallel to the axis represent the angular movements of the magnet which are produced by an increase of terrestrial magnetic force overcoming more completely the torsion-force of the bifilar suspension, or by a diminution of terrestrial force yielding to the torsion-force.

As the spot of light from the horizontal-force-mirror falls on the side of the cylinder opposite to that on which the light from the declination-mirror falls, the same time-scale will not apply to both; it is necessary to prepare a time-scale independently for each.

The following is the calculation by which the scale of horizontal force on the photographic sheet is determined. The distance between the surface of the concave mirror and the surface of the cylinder is 134·436 inches; consequently, one degree of angular motion of the magnet, producing two degrees of angular motion of the reflected ray, moves the spot of light through 4·6927 inches. For the year 1879 the adopted value of variation of horizontal force for one degree of angular motion of the magnet = $\sin .1^{\circ} \times \cot .41^{\circ}. 22^{\circ}.0 = 0.019821$; and the movement of the spot of light for 0·01 part of the whole horizontal force is 2·368 inches. With this fundamental number, the graduations of the pasteboard scale for measure of horizontal force have been prepared.

§ 7. Vertical-Force-Magnet, and Apparatus for observing it.

The vertical-force-magnet in use to 1848 was made by Robinson; that in use from 1848 to 1864, January 20, was by Barrow. The magnet now in use is by

Simms. Its length is 1th 6ⁱⁿ; it is pointed at the ends. After some trials, it was re-magnetized by Mr. Simms on 1864, June 15. Between 1864, August 27, and September 27, a new knife-edge was attached to it, to remedy a defect which, as was afterwards found, arose from a cause that had no relation to the knife-edge. Its supporting frame rests upon a solid pier, built of brick and capped with a thick block of Portland stone, in the western arm of the magnetic basement. Its position is as nearly as possible symmetrical with that of the horizontal-force-magnet in the eastern arm. Upon the stone block is fixed the supporting frame, consisting of two pillars (connected at their bases) on whose tops are the agate planes upon which vibrate the extreme parts of the knife-edge (to be mentioned immediately). The carrier of the magnet is an iron frame, to which is attached, by clamps and pinching screws, a steel knife-edge, about 8 inches long. The steel knife-edge passes through an aperture in the magnet. The axis of the magnet is as nearly as possible transverse to the meridian, its marked end being east. The axis of vibration is as nearly as possible north and south. To the southern end of the iron frame, and projecting further south than the end of the knife-edge, is fixed a small plane mirror, whose plane makes with the axis of the magnet an angle of $52\frac{3}{4}$ nearly. The fixed telescope (to be mentioned) is directed to this mirror, and by reflexion at the surface of the mirror it views a vertical scale (to be mentioned shortly). The height of this mirror above the floor is about 2tt. 10in.6. Before the introduction of the photographic methods, the magnet was placed in a perforation of a brass frame midway between its knife-edges. But since the photographic method was introduced, the magnet has been placed excentrically; the distance of its southern face from the nearest end of the southern knife-edge being nearly 2 inches, and a space of 41 inches in the northern part of the iron frame being left disposable. In this disposable space there is attached to the iron frame by three clips a concave mirror of speculum-metal, with its face at right angles to the length of the magnet; it is used in the photographic system (shortly to be described). Near the north end of the iron frame are fixed in it two screw-stalks, upon which are adjustible screwweights; one stalk is horizontal, and the movement of its weight affects the position of equilibrium of the magnet (which depends on the equilibrium between the moments of the vertical force of terrestrial magnetism on the one hand and of the magnet's center of gravity on the other hand); the other stalk is vertical, and the movement of its weight affects the delicacy of the balance, and varies the magnitude of its change of position produced by a change in the vertical force of terrestrial magnetism.

The whole is inclosed in a rectangular box. This box is based upon the stone block above mentioned; and in it the magnet vibrates freely in the vertical plane. In the south side of the box is a hole covered by glass, through which pass the rays of light from the scale to the plane mirror, and through which they are reflected from the plane mirror to the telescope. And at the cast end is a large hole covered by glass, through which passes the light from the lamp to the

coneave mirror, and through which it is reflected to the photographic cylinder (to be described hereafter).

The telescope is fixed to the west side of the brick pier which supports the stone pier in the upper room carrying the declination-theodolite. Its position is symmetrical with that of the telescope by which the horizontal-force-magnet is observed; so that a person seated in a convenient position can, by an easy motion of the head left and right, observe the vertical-force and horizontal-force-magnets.

The scale is vertical: it is fixed to the pier which carries the telescope, and is at a very small distance from the object-glass of the telescope. Till 1879, December 23, the scale was of pasteboard; on this day a new opal glass scale by Negretti and Zambra was substituted. The wire in the field of view of the telescope is horizontal. The telescope being directed towards the mirror, the observer sees in it the reflected divisions of the scale passing upwards and downwards over the fixed wire as the magnet vibrates. The numbers of the scale increase from top to bottom; so that, when the magnet is placed with its marked end towards the East, increasing readings (as seen with the fixed telescope) denote an increasing vertical force.

Observations relating to the permanent Adjustments of the Vertical-Force-Magnet.

1. Determination of the compound effect of the declination-magnet, and horizontal-force-magnet, and of the iron affixed to the electrometer pole, on the vertical-force-magnet.

The experiments applying to the combined effect of the two magnets are given in the volumes for 1840–1841, 1844, and 1845: and those applying to the electrometer pole in the volume for 1842. It appeared that no sensible disturbance was produced on the magnet formerly in use. No experiments have been made with the new magnet. The electrometer-pole was removed in 1879, June.

2. Determination of the time of vibration of the vertical-force-magnet in the vertical plane.

In the year 1879, vibrations of the vertical-force-magnet were observed on 80 different days, and with readings of various divisions of the scale. The mean time of vibration adopted was 14°018 throughout the year.

3. Determination of the time of vibration of the vertical-force-magnet in the horizontal plane.

1879, December 31. The magnet with all its apparatus was suspended from a tripod in Magnetic Office, No. 6, its broad side being in a plane parallel to the horizon; therefore, its moment of inertia was the same as when it is in observation. A telescope, with a wire in its focus, was directed to the reflector carried by the magnet. A scale of numbers was placed on the floor of the room, at right angles to the long axis of the magnet, or parallel to the mirror. The magnet was observed only at times when it was swinging through a small arc. From 500 vibrations, the mean time of one vibration $=17^{\circ}.255$. This number is used through the year 1879.

4. Computation of the angle through which the magnet moves for a change of one division of the scale; and calculation of the disturbing force producing a movement through one division, in terms of the whole vertical force.

The distance from the scale to the mirror is 186.07 inches, and each division of the scale $=\frac{12}{30.85}$ inches. Hence the angle which one division subtends, as seen from the mirror, is 7′, 11″·19; and therefore the angular movement of the normal to the mirror, corresponding to a change of one division of the scale, is half this quantity, or 3′, 35″·60.

But the angular movement of the normal to the mirror is not the same as the angular movement of the magnet; but is less in the proportion of unity to the cosine of the angle which the normal to the mirror makes with the magnet, or in the proportion of unity to the sine of the angle which the plane of the mirror makes with the magnet. This angle has been found to be $52_4^{\pm 2}$; therefore, dividing the result just obtained by sine $52_4^{\pm 2}$, we have, for the angular motion of the magnet corresponding to a change of one division of the scale, 4'.30''.85.

From this, the value, in terms of the whole vertical force, of the disturbing force, producing a change of one division, is to be computed by the formula, "Value of one division in terms of radius \times cotan. dip $\times \frac{T^{*2}}{T^{2}}$ "; where T is the time of vibration in the horizontal plane, and T the time of vibration in the vertical plane.

For the year 1879, T was assumed = $17^{\circ}.255$, $T = 14^{\circ}.018$, adopted value of dip = $67^{\circ}.37'$. From these numbers, the change of vertical force, in terms of the whole vertical force, corresponding to one division of the scale, is found = 0.000819.

5. Investigation of the temperature-correction of the vertical-force-magnet.

The new or Simms vertical-force-magnet was subjected to experiments by inclosing it in a copper box, and warming it by an injection of hot air, and observing the amount of deviation which it produced on the suspended magnet used in the deflexion-apparatus for absolute measure of horizontal force, at the same time and in the same manner as were the horizontal-force-magnet and the old vertical-force-magnet, in the experiments described in pages xxvii and xxviii. Observations made on 1864, February 20, 25, March 3, 9, gave, for the tangents of the angles of deflection,—

16 obser	vations wit	h marked end E }	an tanner	iture 36:6 Fab	ronheit a	gave 0·172352
18	,,	w1 " "	can tempera	iture oo o ran	rennett, į	gave 0 112002
33	17	marked end E	,,	62.2	,,	0.171657
29	٠,	ι <i>Η</i> ,,	,,		.,	
26	**	marked end E }	,,	93.3	,,	0.171389
27	,,	,, 11)				

From these it appeared that the tangent of the angle of deflection might be represented by—

$$0 \cdot 172522 \, \times \, \left\{ \, 1 \, - \, 0 \cdot 0002233 \, \times \, (t \, - \, 32) \, + \, 0 \cdot 000001894 \, \times \, (t \, - \, 32)^2 \, \right\}$$

The quantity within the brackets (which represents the variation of magnetic power in terms of the whole power of the magnet) shows the same peculiarities as

those found for the other magnets; that the third term is large, and has a sign opposite to that of the second term.

The factor of variation for 1° of Fahrenheit, when $t = 62^{\circ}$, is -0.0001097.

After these observations, the new vertical-force-magnet was re-magnetized by Mr. Simms, on 1864, June 15.

In the beginning of 1868, observations were made in the method already described for the horizontal-force-magnet, by heating the magnetic basement to different temperatures, and observing the scale-reading in the ordinary way. The results are as follows:—

RESULTS OF TEMPERATURE EXPERIMENTS UPON THE VERTICAL-FORCE-MAGNET.

The coefficient of temperature-correction given by these experiments is enormously greater than any that has been found in any previous experiments. Yet there would appear to be no doubt of its accuracy. And it is easy to see that an instrument, subjected to the effects of gravity working differentially on its two ends, is liable to great changes depending on temperature which have no connection with magnetism. For instance, if the point, at which the magnet is grasped by its carrier, is not absolutely coincident with its center of gravity, a sensible change in the space intervening between the grasping point and the center of gravity may be produced by a small change of temperature, and a disturbance of equilibrium and a great change of apparent magnetic position will follow. There appears to be no way of avoiding these evils but by maintaining almost uniform temperature; a condition which has been almost perfectly preserved in the year 1879. In the reductions which follow, no correction is applied for temperature.

The method of observing with the vertical-force-magnet is the following:—

A fine horizontal wire is fixed in the field of view of the telescope, which is directed to the small plane mirror carried by the magnet. On looking into the telescope, the graduations of the fixed vertical seale are seen; and during the oscillations of the magnet, the divisions of the scale are seen to pass alternately upwards and downwards across the wire. The clock-time, for which the position of the magnet is to be determined, is the same as that for the horizontal force magnet. The observer applies his eye to the telescope about two vibrations before the arranged time, and if the magnet is in motion he observes its place at the next four extreme points of vibration; and the mean of these is taken as for the declination-magnet. But if the magnet is apparently at rest, then at one half-time of vibration before the arranged time, and at an equal interval after the arranged time, the reading of the scale is noted; if the reading continues the same that reading is adopted, if there is a slight difference, the mean is taken. The times of observation are usually 1^h, 3^h, 9^h, and 21^h of Greenwich mean time.

The number of instances in 1879 in which the magnet was found in a state of vibration is very small.

A thermometer, the stem and bulb of which reach considerably below the attached scale, is so planted in a nearly upright position on the magnet box, that the bulb projects into the interior of the box. Readings of this thermometer are taken on every week day, at 0^h, 1^h, 2^h, 3^h, 9^h, 21^h, 22^h, and 23^h. Its index error is insignificant. A few readings are taken on Sunday. Self-registering maximum and minimum thermometers were formerly read twice daily, but in consequence of the very small diurnal range of temperature these observations have not been continued.

§ 8. Photographic self-registering Apparatus for Continuous Record of Magnetic Vertical Force.

The concave mirror which is carried by the vertical-force-magnet is 4 inches in diameter; its mounting has been described in the last article. At the distance of about 22 inches from that mirror, and external to the box, is the horizontal aperture, about 0in·3 in length and 0in·01 in breadth, carried by the same stone block which carries the supports of the agate planes. The lamp which shines through this aperture is carried by a wooden stand. The light reflected from the mirror passes through a cylindrical lens with its axis vertical, very near to the cylinder carrying the photographic paper, and finally forms a well-defined spot of light on the cylinder of paper, at the distance of 100.18 inches from the mirror. As the movements of the magnet are vertical, the axis of the cylinder is vertical. The cylinder is about $14\frac{1}{4}$ inches in circumference, being of the same dimensions as those used for the declination and horizontal-force magnets, and for the earth-currents. The forms of the exterior and interior cylinders, and the method of mounting the paper, are in all respects the same as for the declination and horizontal-force magnets; but the cylinder is supported by being merely planted upon a circular horizontal plate (its position being defined by fitting a central hole in the metallic cap of the cylinder upon a central pin in the plate), which rests on anti-friction rollers and is made by chronometer-work to revolve once in twenty-four hours. The trace of the verticalforce-magnet is on the west side of the cylinder.

On the east side, the cylinder receives the trace produced by the barometer (to be described hereafter). A pencil of light from the lamp which is used for the barometer shines through a fixed aperture; and by a system of prisms and a small cylindrical lens, a photographic base-line is traced upon the cylinder of paper, similar to that on the cylinder of the declination and horizontal-force magnets.

The scale for the ordinates of the photographic curve of vertical force is thus computed. Remarking that the radius which determines the range of the motion of the spot of light is double the distance 100·18 inches, and is therefore = 200·36 inches, the formula used in the last section, when applied to $\frac{\text{disturbing force}}{\text{whole vertical force}} = 0·01$, gives value of division = 200·36 × tan. dip × $\left(\frac{\text{T}}{\text{T}'}\right)^2$ × 0·01. Using the values of T, T', and of dip, given on page xxxir, the value of the ordinate of the photographic curve for $\frac{\text{disturbing force}}{\text{whole vertical force}} = 0·01$, thus obtained, is, for the year 1879, 3·211 inches. With this value, the pasteboard scale, used for measuring the photographic ordinates, has been prepared.

§ 9. Dipping Needles, and Method of observing the Magnetic Dip.

The instrument with which all the dips in the year 1879 have been observed, is that which, for distinction, is called Airy's instrument. It is mounted on a stout block of wood in the Magnetic Office No. 7. The following description will probably suffice to convey an idea of its peculiarities:—

The form of the needles, the form of their axes, the form of the agate bearings, and the general arrangement of the relieving apparatus, are precisely the same as those in Robinson's and other instruments. But the form of the observing apparatus is greatly modified, in order to secure the following objects:—

- I. To obtain a microscopic view of the points of the needles, as in the instruments introduced by Dr. Lloyd and General Sir E. Sabine.
- II. To possess at the same time the means of observing the needles while in a state of vibration.
 - III. To have the means of observing needles of different lengths.
- IV. To give an illumination to the field of view of each microscope, directed from the side opposite to the observer's eye, so that the light may enter past the point of the needle into the object glass of the microscope, forming a black image of the needle-point in a bright field of view.
 - V. To give facility for observing by day or night.

With these views, the following form is given to the apparatus:—

The needle, and the bodies of the microscopes, are inclosed in a square box. The base of the box, two vertical sides, and the top, are made of gun-metal (carefully selected to insure its freedom from iron); but the sides parallel to the plane of vibration of the needle are of glass. Of the two glass sides, that which is next the observer is firmly fixed; it is hereafter called "the graduated glass-plate." The other glass side can be withdrawn, to open the box, for inserting the needle, &c.

An axis, whose length is perpendicular to the plane of vibration of the needles, and is as nearly as possible in the line of the axis of the needle, supported on two bearings (of which one is cemented in a hole in the graduated glass-plate, the other being upon a horizontal bar near to the agate support of the needle-axis), carries a transverse arm, about 11 inches long, or rather two arms, projecting about $5\frac{1}{2}$ inches on each side of the axis. Each of these projecting arms carries three fixed microscopes on each side, adapted in position to the lengths of the needles to be mentioned shortly.

The microscope-tube thus carried is not the entire microscope, but so much as contains the object-glass and the field-glass. Upon the plane side of the field-glass (which is turned towards the object-glass), a series of parallel lines is engraved by

etching with fluoric acid. The object-glass is so adjusted that the image of the needle-point is formed upon the plane side of the field-glass; and thus the parallel lines can be used for observing the needle in a state of vibration; and, one of them being adopted as standard, the lines can be used for reference to the graduated circle (to be mentioned). All this requires that there be an eye-glass also for the microscope.

The axis of which we have spoken is continued through the graduated glass-plate, and there it carries another transverse arm parallel to the former, and generally similar to it, in which are fixed three sockets and eye-glasses. Thus, reckoning from the observer's eye, there are the following parts:—

- (1.) The eye-glass.
- (2.) The graduated glass-plate (its graduations, however, not intervening in this part of the glass, the graduated circle being so large as to include, within its circumference, all the microscopes).
- (3.) The field-glass, on the further surface of which the parallel lines are engraved.
 - (4.) The object-glass.
 - (5.) The needle.
 - (6.) The removeable glass side of the box.
 - (7.) The illuminating reflector, to be described hereafter.

The optical part of the apparatus being thus described, we may proceed to speak of the graduated circle.

The graduations of the circle (whose diameter is about 9³₄ inches) are etched on the inner surface of the graduated glass-plate. These divisions (as well as the parallel lines on the field glasses of the microscopes) are beautifully neat and regular, and appear to be superior to those engraved on metal. The same piece of metal, which carries the transverse arms supporting the microscope bodies, carries also two arms with verniers for reading their graduations. These verniers (being adapted to transmitted light) are thin plates of metal, with notches instead of lines. The reading of the verniers is very easy. The portion of the axis which is external to the graduated glass-plate (towards the observer), and which has there, as already stated, two arms for carrying the microscope eye-glasses, has also two arms for carrying the lenses by which the verniers and glass-plate graduations are viewed. These four arms are the radii of a circle, which can be fixed in position by a clamp, attached to the gun-metal casing of the graduated glass-plate, and furnished with the usual slow-motion screw.

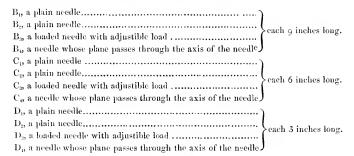

The entire system of the two arms carrying the microscope-bodies, the two arms carrying the microscope eye-glasses, the two arms carrying the verniers, and the two arms carrying the reading-glasses for the verniers, is turned rapidly by means of a button on the external side of the graduated glass-plate, or is moved slowly by means of the slow-motion screw just mentioned.

It now remains only to describe the illuminating apparatus. On the outside of the removeable glass plate, there are supports for the axis of a metallic circle turning in a plane parallel to the plane of needle-vibration. This circle has four slotted radii, which support eight small frames carrying prismatic glass reflectors, each of which can turn on an axis that is in the plane of the circle but transverse to the radius. Two of these reflectors are for the purpose of sending light through the verniers, and therefore are fixed at the same radial distance as the verniers; the other six are intended for sending light past the ends of the needles through the six microscopes, and are therefore fixed at distances corresponding to the fixed microscopes. The circle was originally turned by a small winch near the observer's hand, at present, the winch is removed, as its axis was found to be slightly magnetic. At each observation, it is necessary to turn the circle which carries the reflectors; but this is the work of an instant.

The light which illuminates the whole is a gas-burner, in the line of the axis of rotation. Its rays fall upon the glass prisms, each of which, turning on its axis, can be adjusted so as to throw the reflected light in the required direction.

The whole of the apparatus, as thus described, is planted upon a horizontal plate admitting of rotation in azimuth: the plate is graduated in azimuth, and verniers are fixed to the gun-metal tripod stand. The gas-pipe is led down the central vertical axis, and there communicates by a rotatory joint with the fixed gas-pipes.

The needles adapted for use with this instrument are—

The needles constantly employed are B₁, B₂, C₁, C₂, D₁, D₂.

In discussing carefully the observations taken with this instrument (as well as with other dip-instruments), great trouble was sometimes experienced in determining the zenith-point (or reading of the vertical circle when the points of the needle are in the same vertical). To remedy this, a "zenith-point-needle" was constructed by Mr. Simms, which has since been used as need required. It is a that bar of brass; with pivots similar to those of the dip-needles; and with three pairs of points corresponding to the three lengths of needles used; loaded at one

end so as to take a position perfectly definite with respect to the direction of gravity; observed with the microscopes, and reversed for another observation, exactly as the dip-needles. For each of the different lengths of dip-needles, the zenith-point is determined by observation of that pair of points of the zenith-point-needle whose interval is the same as the length of the dip-needle.

The instrument carries two levels, one parallel to the plane of the vertical circle, the other at right angles to that plane, by means of which the instrument is from time to time adjusted in level. The readings of the first-mentioned level have for some years (since 1867) been recorded at each separate observation of dip, and since the beginning of the year 1875, these observed readings have been regularly employed to correct the apparent value of dip for the small outstanding error of level. The instrument is maintained so nearly level that the correction usually amounts to a few seconds of arc only.

The Dip Instrument and all the needles are examined, at the close of each year, and at other times if thought desirable, by Mr. Dover. A new axis was supplied to the needle B₂ between May 13 and 28.

§ 10. Observations for the absolute Measure of the Horizontal Force of Terrestrial Magnetism.

In the spring of 1861, a Unifilar Instrument, similar to those used in and issued by the Kew Observatory, was procured by the courteous application of General Sir Edward Sabine, from the makers, Messrs. J. T. Gibson and Son; and after having been subjected to the usual examinations, at the Kew Observatory, for determination of its constants (by the kindness of Professor Balfour Stewart), was mounted at the Royal Observatory. Observations with this instrument, which is mounted on a stout block of wood in the Magnetic Office No. 7, were commenced on 1861, June 11, and the instrument is still in use.

The deflected magnet (whose use is merely to ascertain the proportion which the power of the deflecting magnet at a given distance bears to the power of terrestrial magnetism) is 3 inches long, carrying a small plane mirror. The deflecting magnet is 4 inches long; it is a hollow cylinder, carrying in its internal tube a collimator, by means of which its time of vibration is observed in another apparatus. The frame which supports the suspension-piece of the deflected magnet carries also the telescope directed to the magnet-mirror; it rotates round the vertical axis of a horizontal graduated circle whose external diameter is 10 inches. The deflecting magnet is always placed on the east or west side of the deflected magnet, with one end towards the deflected magnet. In the reduction of the observations, the precepts contained in the skeleton form prepared at the Kew Observatory have received the strictest attention.

The following is the explanation of the method of reduction.

The distance between the centers of the deflected and deflecting magnets being known, it is found (from observations made at Kew) that the magnetism of the deflecting magnet is so altered by induction that the following multipliers of its magnetic moment ought to be used in computing the Absolute Force:—

At distance	1 'o foot, factor is	1.00031
	1 .1	1 .00023
	1 .5	81000.1
	1 .3	1.00014
	1 *4	1100011
	1 .2	1 .00000

The correction of the magnetic power for temperature t_0 of Fahrenheit, reducing all to 35° of Fahrenheit, is

0.00013126
$$(t_0-35)$$
 +0.000000259 $(t_0-35)^2$

 A_1 is $\frac{1}{2}$ (distance)³ × sine deflection, corrected by the two last-mentioned quantities, for distance 1 foot; A_2 is the similar expression for distance 1 of; P is $\frac{A_1 - A_2}{A_1 - \frac{A_2}{A_1}}$; but this is not convenient for logarithmic calculation, especially as the values of the logarithms of A_1 and A_2 are, in the calculation, first obtained. The difference between A_1 and A_2 being small, (Log. A_1 — Log. A_2) $\frac{A_1}{\text{modulus}}$ may be written in the numerator in place of A_1 — A_2 , and in the denominator A_1 may be put for A_2 . Making these changes, $P = (\text{Log. } A_1 - \text{Log. } A_2) \frac{1 \cdot 69}{(1 \cdot 69 - 1) \text{ modulus}} = (\text{Log. } A_1 - \text{Log. } A_2) \times 5 \cdot 64$. A mean value of P is adopted from various observations; then m being the magnetic moment of the deflecting magnet, and X the Horizontal component of the Earth's magnetic force, we have $\frac{m}{X} = A_1 \times \left(1 - \frac{P}{1}\right)$ for smaller distance, or $= A_2 \times \left(1 - \frac{P}{1 \cdot 69}\right)$ for larger distance. The mean of these is adopted for the true value of $\frac{m}{X}$.

For computing the value of mX from observed vibrations, it is necessary to know K, the moment of inertia of the magnet as mounted. The value of $\log \pi^2 K$ furnished by Professor Stewart is 1.66073 at temperature 30° , and 1.66109 at temperature 90° . Then putting T for the time of the magnet's vibration as corrected for induction, temperature, and torsion-force, the value of mX is $=\frac{\pi^2 K}{T^2}$. From the combination of this value of mX with the former value of $\frac{m}{X}$ m and X are immediately found. In the year 1878, a new and entirely independent determination of the value of K was made. It very satisfactorily confirmed the adopted value.

It appears, from a comparison of observations given in the Introduction to the Magnetical and Meteorological Observations, 1862, that the determinations with the

Old Instrument (in use to 1861) ought to be diminished by 117 part, to make them comparable with those of the Kew Unifilar.

The computation of the values of m and X was, to the year 1857, made in reference to Euglish measure only, using the foot and the grain as the units of length and weight; but, for comparison with foreign observations of the Absolute Intensity of Magnetism, it is desirable that X should be expressed also in reference to Metric measure, in terms of the millimètre and milligramme. If an English foot be supposed equal to α times the millimètre, and a grain be equal to β times the milligramme, then it is seen that, for the reduction of $\frac{m}{X}$ and mX to Metric measure, these must be multiplied by α^3 and $\alpha^2\beta$ respectively. Hence X^2 must be multiplied by $\frac{\beta}{\alpha}$, and Xby $\sqrt{\frac{\beta}{\epsilon}}$. Assuming that the mètre is equal to 39.37079 inches, and the gramme equal to 15.43249 grains, $\log \sqrt{\frac{3}{2}}$ will be found to be = 9.6637805, and the factor for reducing the English values of X to Metric values will be 0.46108 or $\frac{1}{2\cdot 1689}$. values of X in Metric measure thus derived from those in English measure are given in the proper table. The value of X is sometimes required in terms of the centimetro and gramme, commonly known as the C. G. S. unit (centimètre-gramme-second unit), and values in terms of this unit are obtained by dividing those referred to the millimètre and milligramme by 10.

§ 11. Explanation of the Tables of Results of the Magnetical Observations.

The results contained in this section (so far as relates to the three magnetometers) are founded upon or derived entirely from the measures of the ordinates of the Photographic Curves, and refer to the astronomical day.

Telescope observations of the magnetometers have usually been made four times every day, except on Sunday, on which day three observations have usually been taken. These observations have been employed for forming values of the base lines on the photographic sheets. Finally a new base line, representing a convenient reading in round numbers of the element to which it applies, has been then drawn on each sheet for convenience of further treatment.

Before further discussing the records, the first step usually taken is to divide the days of observation into two groups; in one of which the magnetism was generally so tranquil that it appeared proper to use those days for determination of the laws of diurnal inequality; while in the other group the movements of the magnetic instruments were so violent, and the photographic curves traced by them so irregular, that it appeared impossible to employ them, except by the exhibition of every motion of

the magnet during the day. A similar division into groups had been made in two Memoirs printed in the *Philosophical Transactions*. For the year 1879, however, no days have been found exhibiting sufficient irregularity to render separation necessary.

The whole of the photographic sheets for the year were therefore treated in the following way:—Through each photographic curve a pencil line was drawn, representing, as well as could be judged, the general form of the curve without its petty irregularities. These pencil curves only were then used; and their ordinates were measured, with the proper pasteboard scales, at every hour. These measures being entered in a form having double argument, the vertical argument ranging through the 24 hours of the astronomical day, and the horizontal argument through the days of a calendar month, the means of the numbers standing in the vertical columns give the mean daily value of the element, and the means of the numbers in the horizontal columns the mean monthly value at each hour of the day.

The temperature of the magnetometers was maintained in so great uniformity through each day that the final determination of the diurnal inequalities of horizontal and vertical force should possess great exactitude, although, in regard to vertical force, the magnitude of the temperature co-efficient introduces an element of some uncertainty. It was, however, impossible to maintain similar uniformity of temperature through all the seasons. Following the general principle adopted in recent years, the results are given uncorrected for temperature; corresponding tables of mean temperature being now in all cases added. It is deemed best that, in the yearly volumes, the results should be thus given, as more easily admitting of independent examination. When, as is done from time to time, the results for series of years are collected for general discussion, the temperature corrections are duly taken into account.

It has been the custom, in preceding volumes, to exhibit the varying Declination in the sexagesimal divisions of the circle, and the variable parts of the Horizontal Force and the Vertical Force, in terms of the whole Horizontal Force and whole Vertical Force respectively. This custom is still retained; but since the year 1872 an addition has been made, carrying out the principle suggested by C. Chambers, Esq., Superintendent of the Colaba Observatory, Bombay, that all the variable inequalities should be expressed in terms of Gauss's Magnetic Unit. In applying this principle, reference is made to metrical units of measure and weight instead of British units; a change from the first proposal, which, it is believed, has received the assent of Mr. Chambers. The formulae for converting the original numbers into the new numbers are the following:—

 $\frac{\text{Variations of II. F. in metrical measure}}{\text{II. F. in metrical measure}} = \frac{\text{Variation in former measure}}{\text{Whole value in former measure}}$

from which.

Variation of H. F. metrical
$$=$$
 $\frac{\text{II. F. metrical}}{\text{Former H. F.}} \times \text{former variation.}$

The mean value, for the year, of $\frac{\text{H. F. metrical}}{\text{Former H. F.}} = 1.803$; and this therefore is the factor to be employed for transformation.

Similarly,

$$\label{eq:Variation} \mbox{Variation of V.F. metrical} \ = \ \frac{\mbox{V.F. metrical}}{\mbox{Former V.F.}} \ \times \ \mbox{former variation.}$$

The Former V. F. (in the same manner as Former H. F.) = 1; but the V. F. metrical = H. F. metrical \times tan. dip. The factor is therefore 1.803 \times tan. 67°. 36′. 55″ = 4.3777.

The values given in Tables VIII. and XIII. for the adopted zeros (in metrical units) of the variable forces, are formed by multiplying 0.8600 and 0.9600 (the adopted zeros in the former expressions) by these factors respectively.

For Variation of Declination, expressed in minutes, the metrical factor is $1.803 \times \sin 1' = 0.0005245$.

The measures as referred to the metrical unit (millimètre-milligramme-second), are converted into measures on the centimètre-gramme-second (C. G. S.) system by dividing by 10.

In preceding years, allusion has been made to the occasional dislocations of the curve of Vertical Force. No such dislocation has occurred during the year 1879.

On examining the mouthly values of Vertical Force in each year since the mounting of the Vertical Force Magnet which has been used since 1865, it is remarked that the value for each December is less than that for the preceding January by about $\frac{1}{100}$ part of the whole: a quantity far greater than the change deduced from the combination of Dip and Absolute Horizontal Force. This is undoubtedly caused by gradual diminution of the power of the magnet; its determination is supported by the increase in the time of horizontal vibration.

In the Tables of Results of Observations of the Magnetic Dip, the result of each separate observation of Dip with each of the six needles in ordinary use is given, and also the concluded monthly and yearly values for each needle.

The table giving the results of the observations for Absolute Measure of Horizontal Force requires no particular explanation.

§ 12. Wires and Photographic self-registering Apparatus for continuous Record of Spontaneous Terrestrial Galvanic Currents.

In order to obtain an exhibition of the spontaneous galvanic currents which in some measure are almost always discoverable in the earth, and which occasionally are very powerful, it was necessary to extend two insulated wires from an earth connexion at the Royal Observatory, in two directions nearly at right angles to each other, to considerable distances, where they would again make connexion with the earth. By the kindness of the Directors of the South Eastern Railway Company, to whom the Royal Observatory has on several occasions been deeply indebted, two connexions were made in the year 1862; one to a station near Dartford, at the direct distance $9\frac{3}{4}$ miles nearly, in azimuth (measured from North, to East, South, West) 102° astronomical or 122° magnetical, the length of the connecting wire being about 15² miles; the other to a station near Croydon, at the direct distance 8 miles, in azimuth 209° astronomical, or 229° magnetical, the length of the connecting wire being about 10½ miles. At these two stations connexion was made with earth. The details of the courses were as follows. The wires were soldered to a water pipe in the Magnetic Ground at the Royal Observatory. Thence they entered the Magnetic Basement, and passed through the coils of the galvanometers of the photographic self-registering apparatus (to be shortly described). They were then led up the electrometer mast to a height exceeding 50 feet, and thence swung across the grounds to a chimney above the Octagon Room. They descended thence, and were led to a terminal board in the Astronomical Computing Room, to which an intermediate galvanometer could be attached for eye-observation of the currents. From this point they were led to the "Battery Basement," and, with other wires, passed under the Park to the Greenwich Railway Station, and thence upon the telegraph poles of the South Eastern Railway. One wire branched off at the junction with the North Kent Railway to Dartford, the other at the junction with the main line of railway to Croydon. At both places from 1865, November 20, their connexion with earth was made by soldering to iron waterpipes, as at the Royal Observatory. Previously the Dartford and Croydon earthconnexions had been different.

These wires remained in the places described till the end of 1867. It had been discovered in experience that a much smaller separation of the extreme points of earth-connexion would suffice, and it was conjectured that advantage might arise from making the two earth-connexions of each wire on opposite sides of the Observatory and nearly equidistant from it, instead of making one earth-connexion of each within the Observatory grounds. In 1868, therefore, the following wire-courses were substituted. One wire is connected with earth, by a copper plate, at the Lady Well station of the Mid-Kent Railway; it is thence led to the North Kent Junction with the Greenwich Railway, to the Royal Observatory (for communication with the self-registering apparatus), back to the North Kent Junction, then by North Kent Railway and Angerstein Branch to the Angerstein Wharf, where it is connected with earth by a copper plate at the North Kent Junction, then passes to the Royal Observatory and back to the Junction, and then along the North Kent Railway to the Morden

College end of the Blackheath Tunnel, where it is connected with earth in the same manner. The straight lines connecting the extreme points of the wires cross each other near the middle of their lengths and near the Royal Observatory; the length of the first line is nearly 3 miles, and its azimuth 56° N. to E. (magnetic); that of the second line is nearly $2\frac{1}{2}$ miles, and its azimuth 136°. But, in the circuitous courses above described, the length of the first wire is about 103 miles, and that of the second $6\frac{1}{4}$ miles. These wires were established and brought into use on 1868. August 20. On 1877, September 19, the route of two of the branches was changed. The Angerstein Wharf and Blackheath branches, instead of passing from Greenwich viâ North Kent Junction, now pass along the new railway line through Greenwich, and thence respectively to Angerstein Wharf and Blackheath. The length of the section "Lady Well-Angerstein Wharf" is now about 7½ miles, and that of the section "North Kent Junction-Blackheath" about 5 miles. The names and connexions of the Observatory ends of the four branches were identified in 1870; in 1871, June; again in 1872; on 1873, April 17; on 1874, April 15; 1875, May 6; and 1877, May 15. These were again identified on 1877, October 29, in consequence of the change of route made on 1877, September 19; also on 1879, January 10.

The apparatus for receiving the effects of the galvanic currents consists essentially of two magnetic needles (one for each wire), each suspended by a hair so as to vibrate horizontally within a double galvanic coil, exactly as in an ordinary galvanometer (supposed to be laid horizontally); these coils being respectively in the courses of the two long wires. The number of folds of the wire in each coil was 150 (or 300 in the double coil of each instrument) throughout the year. A current of one kind, in either wire, causes the corresponding needle to turn itself through an angle nearly proportioned to the strength of the current, in one direction; a current of the opposite kind causes it to turn in the opposite direction. These turnings are registered by the following apparatus.

To the carrier of each magnet is fixed a small plane mirror, which receives all the azimuthal motions of the magnet. The light of a gas-lamp passes through a minute aperture, and shines upon the mirror; the divergent pencil is converted into a convergent pencil by refraction through crossed cylindrical lenses (one with axis vertical before the pencil reaches the mirror, and one with axis horizontal where the pencil is received from the mirror), which, under the circumstances, were more convenient than spherical lenses. A spot of light is thus formed upon the photographic paper wrapped upon a cylinder of ebonite, which is covered by a glass cylinder, and made to rotate in twenty-four hours by clock-work, exactly as for the register of the magnetic elements. As in the case of declination and horizontal-force, the two earth currents make their registers upon opposite sides of the same barrel, and upon different parts of the sheet; the same gaslight serving for the illumination of both.

A portion of a zero-line for either record is obtained at any time by simply breaking the galvanic communication.

The photograph records were regularly made, with the wires in the first position, from 1865, March 15, to the end of 1867. Fifty-three days, on which the magnetic disturbances were active, were selected for special examination; and for these the equivalent galvanic currents in the north and west directions were computed, and their effects in producing apparent magnetic disturbances in the west and north directions were inferred. They correspond almost exactly with those indicated by the magnetometers. Then the records for all the days of tranquil magnetism were reduced in the same manner, not for comparison with the magnetometer-results, but for ascertaining the diurnal laws of the galvanic currents. These laws were found to be very different from the laws of magnetic diurnal inequalities. These discussions have been communicated to the Royal Society in two papers, printed respectively in the Philosophical Transactions for 1868 and 1870.

The records with the earth connexions in the new positions have been regularly made since 1868, August 20, but have not yet been discussed.

§ 13. Standard Barometer.

The Barometer is a standard, by Newman, mounted in 1840. It is fixed on the South wall of the West arm of the Magnetic Observatory. The tube is 0ⁱⁿ·565 in diameter; the cistern is of glass. The depression of the mercury due to capillary attraction is 0ⁱⁿ·002, but no correction is on this account applied. The graduated scale which measures the height of the mercury is made of brass, and to it is affixed a brass rod, passing down the inside of one of the upright supports, and terminating in a conical point of ivory; this point in observation is made just to touch the surface of the mercury in the cistern, and the contact is easily seen by the reflected and the actual point appearing just to meet each other. The rod and scale are made to slide up and down by means of a slow-motion screw. The scale is divided to 0ⁱⁿ·05.

The vernier subdivides the scale divisions to 0ⁱⁿ·002; it is moved by a slow-motion screw, and in observation is adjusted so that the ray of light, passing under the back and front of the semi-cylindrical plate carried by the vernier, is a tangent to the highest part of the convex surface of the mercury in the tube.

At the bottom of the instrument are three screws, turning in the fixed part of the support, and acting on the piece in which the lower pivot of the barometer-frame turns, for adjustment to verticality: this adjustment is examined occasionally.

The readings of this barometer, until 1866, August 20⁴, 0⁶, are considered to be coincident with those of the Royal Society's flint-glass standard barometer. On that

day a change was made in the barometer. It had been remarked that the slow-motion-screw at the bottom of the sliding rod (for adjusting the ivory point to the surface of the mercury in the cistern) was partly worn away: and on August 20 the sliding rod was removed from the barometer by Mr. Zambra to remedy this defect. It was restored on 1866, August 30⁴, 3^h. Before the removal of the sliding rod, barometric comparisons had been made with a standard barometer the property of Messrs. Murray and Heath, and with two barometers, Negretti and Zambra, Nos. 646 and 647. While the sliding rod of the Greenwich standard was removed. Negretti and Zambra 647 was used for daily observations. After the new equipment of the standard barometer, another series of comparisons with the same barometers was made: from which it was found (the three auxiliaries giving accordant results) that the readings of the barometer, in its new state, required a correction of -0^{in} 006. This correction has been applied to every observation commencing with that at 1866, August 30^d, 9^h.

In the spring of the year 1877 an elaborate comparison of the Standard Barometers of the Greenwich and Kew Observatories was made under the direction of the Kew Committee. (See *Proceedings of the Royal Society*, vol. 27, page 76.) Mr. Whipple, Superintendent of the Kew Observatory, brought four barometers to Greenwich on three separate occasions. The result of a large number of comparisons showed that the difference between the Greenwich and Kew standards does not exceed 0.001 inch. In this is of course included the above-mentioned correction of $-0^{\text{in-}006}$.

The height of the eistern above the mean level of the sea is 159 feet. This element is founded upon the determination of Mr. Lloyd, in the *Philosophical Transactions*, 1831; the elevation of the eistern above the brass piece inserted in a stone in the transit-room, now the Astronomer Royal's official room (to which Mr. Lloyd refers), being 5^{tt}, 2th.

The barometer has usually been read at 21^h, 0^h, 3^h, 9^h (astronomical), and corrected by application of the index error given above. Every reading has been reduced to the reading which would have been obtained at the temperature 32° of the mercury, and corrected for expansion of the brass scale, by application of the correction given in Table II. (pages 82 to 87) of the "Report of the Committee of Physics" of the Royal Society. For immediate use the mean of the reduced readings has then been taken for each civil day, and finally converted into mean daily reading, by application of the correction inferred from Table XIV. of the "Reduction of Greenwich Meteorological Observations, 1847–1873." These results do not appear in the present volume, but results deduced from the photographic records, as will be further on mentioned (in § 26).

In the printed record of the barometrical and all other meteorological observations, the day is to be understood, generally, as defined in civil reckoning.

l

§ 14. Photographic self-registering Apparatus for continuous Record of the Readings of the Barometer.

The Photographic self-registering Apparatus for continuous Record of Magnetic Vertical Force is furnished (as has been stated) with a vertical cylinder covered with photographic paper and revolving in 24 hours. North of the surface of this cylinder, at the distance of about 30 inches, is a large syphon barometer, the bore of the upper and lower extremities of its arms being about 1.1 inch. A glass float, for which at the beginning of the year 1879 a metallic float was substituted, partly immersed in the mercury of the lower extremity is partially supported by a counterpoise acting on a light lever, leaving a definite part of the weight of the float to be supported by the mercury. This lever is lengthened to carry a vertical plate of opaque mica having a small horizontal slit, whose distance from the fulcrum is nearly eight times the distance of the point of attachment of the float wire, and whose movement, therefore, is nearly four times the movement of the column of a cistern-barometer. Through this slit the light of a lamp, collected by a cylindrical lens, shines upon the photographic paper. The barometer rests on a platform which can be raised or lowered by a screw, so as to bring the photographic trace to a convenient part of the sheet. As regards the effect of temperature, it will be understood, from the construction of the apparatus, that the record is influenced only by the expansion of the column of mercury (about 4 inches in length) in the lower tube of the barometer; and from this circumstance, in combination with the near uniformity of temperature maintained in the basement, no perceptible effect is produced on the register.

The scale of time is established by means of occasional interruptions of the light, and the scale of measure is established by comparison with occasional eye-observations

This barometer was brought into use in 1848, but its indications were not satisfactory till the mercury was boiled in the tube by Messrs. Negretti and Zambra on 1853, August 18, since which time they have appeared unexceptionable.

A discussion of the photographic records of the Barometer from 1854 to 1873 is published in the "Reduction of Greenwich Meteorological Observations, 1847–1873."

§ 15. Thermometers for ordinary Observation of the Temperature of the Air and of Evaporation.

The Dry-Bulb Thermometer, the Wet-Bulb Thermometer, the Maximum Self-Registering Thermometers, both dry and wet, and the Minimum Self-Registering Thermometers, dry and wet, all for determination of the temperature of the air and

of evaporation, are mounted on a revolving frame whose fixed vertical axis is planted in the ground. From the year 1846 to 1863 the post forming the vertical axis was about 23 feet south (astronomical) of the S.W. angle of the south arm of the Magnetic Observatory; in 1863 it was moved to its present position, about 35 feet south (astronomical) of the S.W. angle. A frame revolves on this post, consisting of a horizontal board as base, of a vertical board projecting upwards from it connected with one edge of the horizontal board, and of two parallel inclined boards (separated about three inches) connected at the top with the vertical board, and at the bottom with the other edge of the horizontal board. The outer inclined board is covered with zinc. The air passes freely between all these boards. In September of the year 1878 some small additions were made, mainly with the object of better protecting the thermometers from the influence of radiation.

The dry and wet-bulb thermometers are attached to the outside, and near the center of the vertical board; their bulbs are about 4 feet above the ground and projecting from 2 inches to 3 inches below the horizontal board. The maximum and minimum thermometers for air are placed towards one vertical edge, and those for evaporation towards the other vertical edge, with their bulbs at almost the same level, and near to those of the dry and wet-bulb thermometers. Above the thermometers is a small projecting roof to protect them from rain. The frame is always turned with the inclined side towards the sun. It is presumed that the thermometers are thus sufficiently protected.

The graduations of all the thermometers used in the Royal Observatory since the year 1840 rest fundamentally upon those of a Standard Thermometer, the property of Mr. Glaisher, which derives its authority from comparison with original thermometers constructed by the late Rev. R. Sheepshanks about the years 1840–1843, in the course of his preparations for the construction of the National Standard of Length. The whole of the radical determinations of Freezing Point, Boiling Point, and Subdivision of Volume of Tube, were made by Mr. Sheepshanks with the ntmost care: it is believed that these were the first original thermometers that had been constructed in England for many years. This thermometer continued to be the standard of reference until June of the year 1875.

By the kindness of the Kew Committee of the Royal Society, a new Kew Standard Thermometer, No. 515, was, in the year 1875, supplied to the Royal Observatory; and, commencing with the month of July of that year, all thermometers have been compared with the new standard, which will hereafter be referred to as the R. O. standard.

In order to determine whether any sensible difference exists between the indications of Mr. Glaisher's standard and those of the R. O. standard, the errors of all thermometers that, in the year 1875, had been recently referred to both standards, were collected for comparison. The details of this comparison will be found in the

Introduction to the Magnetical and Meteorological Observations for 1875, page xlriii. The result arrived at was that the standards were practically identical.

The Dry-Bulb and Wet-Bulb thermometers by Horne and Thornthwaite remained in use until November 13. To February 28 the dry-bulb thermometer required correction as follows:—

From March 1 to November 13 the corrections applied were:—

```
        Below
        63
        subtract
        1°2

        Above
        65
        1°3
```

The wet-bulb thermometer to February 28 required correction as follows:-

```
      Below
      55°
      ...
      subtract
      1° o

      Between
      55 and 70

      0° 7

      Above
      80
      0° 6
```

From March 1 to November 13 the corrections applied were:-

```
      Below
      55
      subtract 1°2

      Between
      55 and 70
      1°1

      .
      70 and 80
      0°9

      Above
      80
      0°8
```

On November 14 the wet-bulb thermometer was accidentally broken. Both thermometers were dismounted, and, pending the construction of a new pair of thermometers, two thermometers by Watkins and Hill (the property of Mr. Ellis) were until December 3 employed. One thermometer, marked B, used as dry-bulb, required correction as follows:—

Below	33 subtract o	٠,
	34 and 37 o	
	38 and 40 o	
٠,	41 and 44 o	٠,
••	45 and 55 o	٠5

On December 3 a new pair of thermometers by Negretti and Zambra was brought into use. These thermometers, No. 45354 as dry-bulb, and No. 45355 as wet-bulb, required no correction.

The self-registering thermometers for temperature of air and evaporation are by Negretti and Zambra. The construction of the thermometers for maximum temperature is as follows.

There is a small detached piece of glass in the tube, at the bent part (near the bulb), through which the piece of glass cannot pass down. The column of mercury in rising is forced through the contraction produced by the piece of glass; but in falling it is unable to pass the glass, and the lower mass of mercury descends into the bulb, leaving a vacant space below the glass, and a portion of the mercury above it. The piece of glass operates as an efficient valve. The thermometer used for maximum temperature of the air was No. 8527; it required a subtractive correction of 0.9.

The maximum wet-bulb thermometer until February 25, when it was accidentally broken, was No. 1575. Its corrections were as follows:—

Below	55subtract	0.3
Above	55	0.1

There was no maximum wet-bulb thermometer in use from February 25 until March 21. On the latter-mentioned day Negretti and Zambra No. 44285 was brought into use. It required correction as follows:—

Below	55	0.0
Above	55 subtract	0.1

The minimum self-registering thermometers by Negretti and Zambra are alcohol thermometers (on Rutherford's principle). A sliding glass index allows the alcohol in rising to pass above it, but is drawn down by the peculiar action of the bounding surface of the fluid when it sinks. The readings of that for minimum temperature of the air, No. 4386, required until February 28 a subtractive correction of 0°·3. From March 1 no correction was applied. The minimum wet-bulb, No. 3627, required an additive correction of 0°·9.

The eye-readings of the dry-bulb and wet-bulb thermometers have usually been taken at the hours (astronomical reckoning) 21^h, 0^h, 3^h, 9^h, and corrected by application of the corrections already given. For immediate use the means of the corrected readings of the dry-bulb and wet-bulb thermometers have been taken and converted into mean daily readings, by the application of a correction inferred from Table LI. of the "Reduction of Greenwich Meteorological Observations, 1847–73,"

but the results do not appear in this volume, the photographic records being now employed, as will be further on explained (in § 26).

§ 16. Photographic self-registering Apparatus for continuous Record of the Readings of the Dry-Bulb and Wet-Bulb Thermometers.

About 28 feet south (magnetic) of the south-east angle of the south arm of the Magnetic Observatory, and about 25 feet east of the thermometers for eye-observations, is an open shed 10 ft. 6 in. square, standing upon posts 8 feet high, under which are placed the photographic thermometers, the dry-bulb thermometer towards the east, and the wet-bulb thermometer towards the west. The bulbs of the thermometers are 8 inches in length, and 0.4 inch internal bore, and their centers are about 4 feet above the ground. The bulb of the thermometer employed as wet-bulb is covered with muslin throughout its whole length, which is kept moist by means of capillary passage of water along cotton wicks leading from a vessel filled with water.

There are small adjustments admitting the raising or dropping of the thermometers, so that the register of their changing readings may fall on a convenient part of the paper. The thermometer frames are covered by plates having longitudinal apertures, so narrow, that any light which may pass through them is completely, or almost completely, intercepted by the broad flat column of mercury in the thermometer-tube. Across these plates a fine wire is placed at every degree; those at the decades of degrees, and also those at 32°, 52°, and 72°, being coarser than the others. A gas lamp is placed about 9 inches from each thermometer (east of the dry bulb and west of the wet bulb), and its light, condensed by a cylindrical lens, whose axis is vertical, shines through the thermometer-tube above the surface of the mercury. and forms a well-defined line of light upon the photographic paper, which is wrapped around the cylinder. The axis of this cylinder is vertical; its mounting is in all respects similar to that of the Vertical Force cylinder. As the cylinder, covered with photographic paper, revolves under the light, which passes through the thermometer-tube, it receives a broad sheet of photographic trace, whose breadth (in the direction of the axis of the cylinder) varies with the varying height of the mercury in the thermometer-tube. Parts of the light in its passage are intercepted by the wires placed across the tube at every degree, and there are, therefore, left upon the paper corresponding lines in which there is no photogenic action. In consequence of a want of complete uniformity in different parts of the photographed scales, owing to inequality in the bore of the tube in both thermometers, new thermometers with better tubes were prepared by Messrs. Negretti and Zambra, and mounted on 1878. November 1. By this means the scales on the paper were rendered quite uniform.

The cylinder was at first made to revolve in 48 hours; the daily photographic traces of the two thermometers were thus simultaneously registered on opposite sides of the cylinder, sometimes slightly intermixing. The length of the glass cylinder used till 1869, March, is 13½ inches, and its circumference is about 19 inches. On 1869, March 5, an ebonite cylinder was introduced, whose length is 10 inches, and circumference about 19 inches; and at a later time the cylinder was made to revolve in 50 hours instead of 48 hours, to insure the separation of the records of the two thermometers. In March of the year 1878 the time of revolution was further increased to 52 hours.

The photographic records of the dry-bulb and wet-bulb thermometers have been discussed from 1848 to 1868. The results exhibit the diurnal inequality of the temperature of the air and of evaporation, as grouped by months, as grouped by periods of high and low temperature, as grouped by periods of high and low atmospheric pressure, as grouped by cloudless or overeast sky, and as grouped by directions of the wind. They are published in the "Reduction of Greenwich Meteorological Observations, 1847–1873."

§ 17. Thermometers for Solar Radiation and Radiation to the Sky.

The thermometer for Solar Radiation, which to the end of the year 1864 was placed in an open box about 10 feet south of the south-west angle of the south arm of the Magnetic Observatory, is now laid on the grass, near the same place.

The thermometer is a self-registering maximum mercurial thermometer of Negretti and Zambra's construction (No. 5964); its bulb is blackened, and enclosed in a glass sphere from which the air has been exhausted. Its graduations are correct, and the numbers inserted in the tables are those read from the instrument without alteration. The thermometer is read at 21^h, 0^h, 3^h, and 9^h daily; the highest of these readings is adopted as the maximum for the day. On April 17 the thermometer No. 5964 was broken. A new thermometer, Negretti and Zambra No. 43418, was brought into use on April 18. It required no correction.

The use of a thermometer with blackened bulb not inclosed in an exhausted sphere was discontinued at the end of 1865.

The thermometer for radiation to the sky is placed near to the Solar Radiation thermometer, with its bulb resting on short grass, and fully exposed to the sky. It is a self-registering minimum spirit thermometer of Rutherford's construction, Horne and Thornthwaite No. 3120. Its graduation is practically correct, and the numbers inserted in the table are those read from the scale without alteration. It is read every day at 21^h, and, except in summer, also at 9^h.

§ 18. Thermometers sunk below the Surface of the Soil at different Depths.

These thermometers were made by Messrs. Adie of Edinburgh, under the immediate superintendence of the late Professor J. D. Forbes. The graduation was made by Professor Forbes himself.

The thermometers are four in number. They are all placed in one hole in the ground, the diameter of which in its upper half is I foot, and in its lower half about 6 inches. Each thermometer is attached in its whole length to a slender piece of wood, which is planted in the hole with it. The place of the hole is 20 feet south (magnetic) of the extremity of the south arm of the Magnetic Observatory, and opposite the center of its south front.

The soil consisted of beds of sand; of flint-gravel with a large proportion of sand; and of flints with a small proportion of sand, cemented almost to the consistency of pudding-stone. Every part of the gravel and sand extracted from the hole was perfectly dry.

The bulbs of the thermometers are cylindrical, 10 or 12 inches long and 2 or 3 inches in diameter. The bore of the principal part of the tubes, from the bulb to the graduated scale, is very small. In that part to which the scale is attached, the tube is larger.

The thermometer No. 1 was dropped into the hole to such a depth that the center of its bulb was 24 French feet (25.6 English feet) below the surface: then dry sand was poured in till the hole was filled to nearly half its height. Then No. 2 was dropped in till the center of its bulb was 12 French feet below the surface: No. 3 and No. 4 till the centers of their bulbs were respectively 6 and 3 French feet below the surface; and the hole was then completely filled with dry sand. The upper parts of the tubes, carrying the scales, were left projecting above the surface: No. 1 by 27.5 inches, No. 2 by 28.0 inches, No. 3 by 30.0 inches, and No. 4 by 32.0 inches. Of these lengths, the parts 85, 100, 110, and 145 inches, respectively, are tube with narrow bore.

The projecting parts of the tubes are protected by a wooden case or box fixed to the ground; the sides of the box are perforated with numerous holes, and it has a double roof. In the North face of this box is a large plate of glass through which the thermometers are read. Within the box are two smaller thermometers, one (No. 5) whose bulb is sunk one inch in the ground, and one (No. 6) whose bulb is in the free air nearly in the center of the box.

The fluid of the four long thermometers is alcohol tinged with a red colour.

The lengths of 1' on the scales of Nos. 1, 2, 3 and 4, are respectively about 19 inch, 14 inch, 09 inch, and 05 inch; and the ranges of the scales, as first mounted, were, 43°0 to 52°7, 42°0 to 56°8, 39°0 to 57°5, and 34°2 to 64°5.

These ranges for Nos. 2, 3, and 4, were found to be insufficient in some years, particularly those of Nos. 3 and 4, or the thermometers sunk to the depth of 6 feet and 3 feet.

In 1857, June 22, Messrs, Negretti and Zambra removed from Nos. 3 and 4 a quantity of fluid corresponding to the extent of 5 on their scales, and the scales of these two thermometers were then lowered by that linear extent, making the readings the same as before.

In subsequent years it was found that the amount of fluid removed was somewhat too great, for at the lower end of the scale the 6-foot thermometer sometimes fell below the limit of its scale or 44° ; and the 3-foot thermometer below 39° 0; in which cases the alcohol sank into the capillary tube.

The readings at the early part of the series were at times defective at high temperatures, but always complete at low temperatures; afterwards, they were generally complete at high temperatures, and at times defective at low temperatures. The two combined, however, will enable us to complete all readings.

On 1869, July 21, Mr. Zambra removed fluid from No. 1 to the amount of 2°.7, and from No. 2 to the amount of 1°.5, and inserted in No. 4 fluid to the amount of 1°.5. The scales were re-engraved, to make the reading at every temperature the same as before.

In 1877, May, new opal glass scales were applied to these thermometers, by which the facility of reading is much increased.

The ranges of the scales are now,—for No. 1, 46° 0 to 55° 5; for No. 2, 43° 0 to 58° 0; for No. 3, 44° 0 to 62° 0; and for No. 4, 37° 0 to 68° 0.

These thermometers are read every day, at noon, and the readings appear in the printed volumes without correction. The index errors of Nos. 1, 2, 3, and 4 are unknown, but from comparisons made with the standard thermometer in November 1879 it would appear that No. 5 reads too high by 0°2, and No. 6 too high by 0°4.

The observations of these thermometers from 1846 to 1859 have been elaborately reduced by Professor Everett; the results are printed as an Appendix to the Greenwich Observations for 1860. Abstracts of the observations of these thermometers (giving mean monthly temperatures) for the period 1847 to 1873 have since been published in the "Reduction of Greenwich Meteorological Observations 1847–1873."

§ 19. Thermometers immersed in the Water of the Thames.

The self-registering maximum and minimum thermometers for determining the highest and lowest temperatures of the water of the Thames are observed every day at 9° a.m.

The thermometers, inclosed in a wooden trunk, were originally attached to the side of the "Dreadnought" hospital ship. Commencing with 1871, January 12, they were attached to the Police Ship "Scorpion," moored in Blackwall Reach. In the month of May 1874, the wooden trunk was shifted from the "Scorpion" to the "Royalist," moored in the same place. The first readings with the thermometers in the last-mentioned position were taken 1874, May 5.

The wooden trunk, about 5 feet in height, and closed at the bottom, is firmly fixed to the side of the "Royalist;" the bottom and the sides, to the height of 3 feet, are perforated with a great number of holes, so that the water can easily flow through; the thermometers are suspended within this trunk so as to be about 2 feet below the surface of the water, and 1 foot from the bottom of the trunk.

The observations have been made by the Resident Inspector on board, by permission of Lieut.-Col. Sir Edmund Y. W. Henderson, R.E., K.C.B., Commissioner of Metropolitan Police.

The thermometer used for maximum temperature (a thermometer on Phillips's principle) is Horne and Thornthwaite No. 22242; that for minimum temperature is Horne and Thornthwaite No. 22243. Both thermometers require an additive correction of 0°3.

On October 18 the "Royalist" received such damage in consequence of another vessel having come into collision with her that she was removed, on October 19, into the West India Dock. The temperatures given from October 20 to 25 are those of the water of the dock. The readings were then discontinued. The ship was not again moored in the river, but in the year 1880 was placed on the river bank, near high-water mark, in which position no further observations of the temperature of the water could be made. This series of observations is now therefore terminated.

§ 20. Osler's Anemometer.

This anemometer is fixed above the north-western turret of the ancient part of the Observatory, and is self-registering: it was made by Newman, on a plan furnished by A. Follett Osler, Esq., F.R.S., but has received several changes since it was originally constructed. A large vane, which is turned by the wind, and from which a vertical spindle proceeds down nearly to the table in the north-western turret, gives motion by a pinion upon the spindle to a rack-work carrying a pencil. In 1866 the vane-shaft was made to bear upon anti-friction-rollers running in a cup of oil. The pencil makes a mark upon a paper affixed to a board which is moved uniformly in a direction transverse to the direction of the rack-motion. The movement of the board is effected by means of a second rack connected with the pinion of a clock,

The paper has lines printed upon it corresponding to the positions which the pencil must take when the direction of the vane is N, E, S, or W; and also has transversal lines corresponding to the positions of the pencil at every hour. The original adjustment for azimuth, made in the year 1841, was obtained by observing, from a certain point on the roof of the octagon room, the time of passage of a star behind the vane-shaft, and computing from that observation the azimuth, by which means the direction plate, placed above the registering table, was adjusted to position. Then, on a calm day, the direction pointer (to which reference is made in adjusting, on the sheet, the position of the direction pencil) was brought into exact correspondence with the large vane. The adjustment for azimuth was further verified by observation of stars in the year 1850, and again in the year 1878. A fixed mark, at a known azimuth, is now attached to the north-eastern turret for the purpose of at any time examining the position of the direction plate.

For the pressure of the wind the construction originally arranged by Mr. Osler was in use till the middle of 1866, when certain modifications were made in it by Mr. Browning, as represented in Figure 3 of the engraving at the end of the Introduction to the volume for 1866. To the vane-shaft is attached a rectangular frame C, which rotates with the vane. To this frame are firmly attached the ends of four strong springs D, which rise from the point of attachment in a vertical direction, are then bent so as to descend below the frame C, and are then bent upwards so as to rise a short distance, where they terminate, each of them thus forming a large hook. To the interior of each strong spring, near to its upper bend, is affixed a very weak spring, which descends free into the lower bend or hook of the strong spring, so that its lower end may be moved by a light pressure till it reaches and takes bearing against the bent-up part of the strong spring, after which it cannot be further moved without moving the strong spring, and will therefore require much greater pressure. The four ends of these four light springs carry the circular pressure-plate A by the following connexions. The two which are farthest from A, or which are below the wide part of the vane, are united by a light horizontal cross-bar G; and from the ends of these springs proceed four light bars E, which are attached to points of the pressure-plate A, near its circumference. The two ends of light springs which are nearest to A are also united by a light horizontal cross bar, which is attached to a projection from the center of the plate A. (The diagonal lines upon A, in the diagram, represent indistinetly two strengthening edge-bars upon the pressure-plate, and the projection above mentioned is fixed to their intersection.) The weight of the pressure-plate thus rests entirely on the slender springs; it is held steadily in position, as regards the opposition to the wind, and it moves without sensible friction. A light wind drives it through a considerable space, until the ends of one pair of light springs touch their large hooks; then for every additional pound of pressure the movement

lx

is smaller, till the ends of the other pair of light springs touch their large hooks; after this the movement for every additional pound of pressure is still further diminished. This apparatus was arranged by Mr. Browning. The communication with the pencil below is similar to that in the first construction: the cord and pulley are omitted in the drawing to avoid confusion.

The pressure-pencil below is carried by a radial bar, whose length is parallel to the scale of hours; it is brought to zero by a light spring.

The area of the pressure-plate is 2 square feet, or double that in the old construction. The scale of indications on the recording sheet was determined experimentally as in the old instrument; yet it was remarked that the pressures of wind per square foot appeared generally greater than formerly. It was suspected that the inertia of the tension-weight acting against the pressure-spring, and that of the pencil-weight, may have produced an injurious effect; both these weights were replaced by springs, 1872, February 21. The pencil-spring has since been removed and weight applied as necessary.

The scale for small pressures is much larger, and their indications much morecertain than formerly. A pressure of an ounce per square foot is clearly shown.

A rain gauge of peculiar construction is carried by this instrument, by which the fall of rain is registered with reference to the time of the fall. It is described in § 22.

A fresh sheet of paper is applied to this instrument every day at 225 mean solar time.

§ 21. Robinson's Anemometer,

Two instruments, constructed on the principle described by Dr. Robinson in the Transactions of the Royal Irish Academy, vol. xxii., have been at different periods in use. The first, made by Negretti and Zambra, and used from 1859, October, to 1866, October, did not give a continuous record, and required to be read off from time to time. The second instrument, made by Mr. Browning, and used since 1866, October, gives a continuous register. Both instruments have been mounted above the small building on the roof of the Octagon Room. The principal parts of the Browning instrument are represented in Figures 1 and 2 of the engraving at the end of the Introduction for 1866. The motion is given (as in the former instrument) by the pressure of the air on four hemispherical caps, the distance of the center of each from the axis of rotation being 15:00 inches. The foot of the axis is a hollow flat cone bearing upon a sharp cone which rises up from the base of a cup of oil. The horizontal arms are connected with a vertical spindle, upon which is an endless screw working in a toothed wheel connected with a train of wheels, furnished with indices capable

of registering one mile and decimal multiples of a mile up to 1,000 miles. A pinion C upon the axis of one of the wheels (which, in the figure, occupies a place too high) acts in a rack J, drawing it upwards by the ordinary motion of the revolving cups. The rack is pressed to the pinion by a spring, and, when it has been drawn up, it can be pressed by hand in opposition to the spring so as to release it from the pinion, and can then be pushed down, again to be raised by the action of the wheel-work. The rack is connected at the bottom with a sliding rod D, which passes down into the chamber below, where it draws up the sliding pencil-carrier E. The pencil F, which it carries, traces its indications upon the sheet of paper wrapped round a barrel, whose axis is vertical, and which by spindle connexion with the clock H is made to revolve in 24 hours. The revolving cups and wheel-work are so adjusted that a motion of the pencil upwards of one inch represents a motion of the air through 100 miles. The curve traced upon the barrel exhibits, therefore, the aggregate of the air's movements, and also the air's velocity, at every instant of the day.

In the year 1860, on July 3, 4, and 13, experiments were made in Greenwich Park, with the instrument by Negretti and Zambra, then in use, to ascertain the correctness of the theory of Robinson's anemometer; the point to be verified being that the scale of the instrument, founded on the supposition that the horizontal motion of the air is about three times the space described by the centers of the cups, is correct.

A post about 5 feet high with a vertical spindle in the top was erected, and on this spindle turned a horizontal arm, carrying at the extremity of its longer portion Robinson's anemometer, and on its shorter portion a counterpoise. The distance from the vertical spindle of the post to the vertical axis of the anemometer was 17 ¹⁶ 8^{16,17}. The reading of the dial was taken, and then the arm was made to revolve in the horizontal plane 50 or 100 times, an attendant counting the number of revolutions, and the reading of the dial was again taken. In this manner 1,000 revolutions were made in the direction N.E.S.W.N., and 1,000 revolutions in the direction N.W.S.E.X. In some of the experiments the air was sensibly quiet, and in others there was a little wind; the result was.

For a movement of the instrument through one mile.

The results from rapid revolutions and from slow revolutions were sensibly the same.

This may be considered as sufficiently confirming the accuracy of the theory.

§ 22. Rain Gauges.

The rain-gauge connected with Osler's anemometer is 50 feet 8 inches above the ground, and 205 feet 6 inches above the mean level of the sea. It exposes to the rain an area of 200 square inches (its horizontal dimensions being 10 by 20 inches).

The collected water passes through a tube into a vessel suspended in a frame by spiral springs, which lengthen as the water accumulates, until 0.25 of an inch is collected in the receiver; it then discharges itself by means of the following modification of the syphon. A copper tube, open at both ends, is fixed in the receiver, in a vertical position, with its end projecting below the bottom. Over the top of this tube a larger tube, closed at the top, is placed loosely. The smaller tube thus forms the longer leg, and the larger tube the shorter leg, of a syphon. The water, having risen to the top of the smaller tube, gradually falls through it into the uppermost portion of a tumbling bucket, fixed in a globe under the receiver. When full, the bucket falls over, throwing the water into a small pipe at the lower part of the globe; the water completely fills the bore of the pipe; its descent causes an imperfect vacuum in the globe, sufficient to cause a draught in the longer leg of the syphon, and the whole contents run off. After leaving the globe, the water is carried away by a waste-pipe attached to the building. The springs at the same time shorten and raise the receiver. The descent and ascent of the water-vessel move a radius-bar which carries a pencil; and this pencil makes a trace upon the paper carried by the sliding board of the self-registering anemometer. As the trace is rather long in proportion to the length of the radius-bar, the bar has now been furnished by Mr. Browning with a "parallel motion," which makes the motion of the pencil sensibly straight.

The scale on the printed paper was adjusted by repeatedly filling the water-vessel until it emptied itself. The weight of the quantity necessary to cause one discharge being thus accurately determined, its bulk was ascertained, and this bulk being divided by the area of the surface of the rain receiver gave the corresponding measure of the scale.

A second gauge, with an area 77 square inches nearly, is placed close to the preceding, the receiving surface of both being on the same horizontal plane.

A third gauge is placed on the roof of the Octagon room, at 38 feet 4 inches above the ground, and 193 feet 2 inches above the mean level of the sea. It is a simple cylinder gauge, 8 inches in diameter and about 50\(^1_4\) square inches in area. The height of the cylinder is 13\(^1_2\) inches; at the depth of 1 inch from the top within the cylinder is fixed a funnel (an inverted cone) of 6 inches perpendicular height; with the point of this funnel is connected a tube, \(^1_5\) of an inch in diameter, and 1\(^1_2\) inche in length; \(^3_4\) of an inch of this tube is slightly curved, and the remaining \(^3_4\) of an

inch is bent upwards, terminating in an aperture of $\frac{1}{8}$ of an inch in diameter. By this arrangement, the last few drops of water remain in the bent part of the tube, and the water is some days evaporating. The upper part of the funnel or bore of the cone is connected with a brass ring, which has been turned in a lathe, and this is connected with a circular piece 6 inches in depth, which passes outside the cylinder, and rests in a water joint, attached to the inner cylinder, and extending all round.

A fourth gauge is placed on the roof of the Magnetic Observatory. Its receiving surface is 21 feet 9 inches above the ground, and 176 feet 7 inches above the mean level of the sea. It is similar in construction to the third gauge, and has been substituted for that placed, until the end of the year 1878, above the Library, the latter having been in some degree overshadowed by the dome of the Great Equatoreal. The elevation of the new gauge is a few inches only less than that of the old gauge.

A fifth gauge is planted on the roof of the Photographic Thermometer shed, 10 feet above the ground, and 164 feet 10 inches above the mean level of the sea. Its construction is the same as that of the third gauge.

A sixth gauge is a self-registering rain-gauge on Crosley's construction, made by Watkins and Hill. The surface exposed to the rain is 100 square inches. collected water falls into a vibrating bucket, whose receiving concavity is entirely above the center of motion, and which is divided into two equal parts by a partition whose plane passes through the axis of motion. The pipe from the rain-receiver terminates immediately above the axis. Thus that part of the concavity which is highest is always in the position for receiving water from the pipe. When a certain quantity of water has fallen into it, it preponderates, and, falling, discharges its water into a cistern below; then the other part of the concavity receives the rain, and after a time preponderates. Thus the bucket is kept in a state of slow vibration. To its axis is attached an anchor with pallets, which acts upon a toothed wheel by a process exactly the reverse of that of a clock-escapement. This wheel communicates motion to a train of wheels, each of which carries a hand upon a dial-plate; and thus inches, tenths, and hundredths are registered. The gauge is placed on the ground, 21 feet South of the Magnetic Observatory, and 156 feet 6 inches above the mean level of the sea.

The seventh and eighth gauges are placed near together, about 16 feet south of the Magnetic Observatory, 5 inches above the ground, and 155 feet 3 inches above the mean level of the sea. They are similar in construction and area to No. 3. These gauges are sunk about 8 inches in the ground.

Another gauge (the ninth) was established at the end of the year 1875 at the Police ship "Royalist," moored in Blackwall Reach. Its receiving surface is 17 feet above the level of the river. It was brought into use on 1876, January 1. The "Royalist" was moved into the West India Dock on October 19, in consequence of

an accident (see page *lviii*), and remained in dock until the end of the year. The exposure of the gauge in the latter position was not quite so good as in the river. The observations terminate at the end of the year 1879.

All these gauges, except No. 8, are read at 21^h daily; in addition, Crosley's gauge and No. 7 are read daily at 9^h. No. 8 is read at the end of each month only, to check the summation of the daily readings of No. 7. All are read at midnight of the last day of each month.

§ 23. Electrometer.

Until the year 1877 the electricity of the atmosphere was collected by means of an insulated exploring wire suspended from the top of the Octagon Room to the top of a pole 79 feet high situated close to the north arm of the Magnetic Observatory; thence the wire was led down the pole and brought into connexion with an insulated receiving bar within the Magnetic Observatory, with which various electrometers and other apparatus could be brought into communication at pleasme. The several annual volumes, until the year 1877, contain detailed descriptions of all these arrangements. The action of this apparatus was frequently unsatisfactory, and its use was altogether discontinued in August of the year 1877, in view of the establishment of a Thomson's self-recording electrometer, received from Mr. White, of Glasgow, in the same year. For a very full description of the principle of this instrument reference may be made to Sir W. Thomson's "Report on Electrometers and Electrostatic Measurements," contained in the British Association Report for the year 1867.

It will be sufficient here to give a general description of the instrument which has been planted in the Upper Magnet Room on the slate slab which carries the suspension piece of the Horizontal Force Magnet. A thin flat needle of aluminium. carrying immediately above it a small light mirror, is suspended, on the bifilar principle, by two silk fibres from an insulated support within a large Leyden jar. A little strong sulphuric acid is placed in the bottom of the jar, and from the lower side of the needle depends a platinum wire, kept stretched by a weight, which connects the needle with the sulphuric acid, that is with the inner coating of the jar. A positive charge of electricity being given to the needle and jar, this charge is easily maintained at a constant potential by means of a small electric machine or replenisher forming part of the instrument, and by which the charge can be either increased or decreased at pleasure. A gauge is provided for the purpose of indicating at any moment the amount of charge. The needle hangs within four insulated quadrants, which may be supposed to be formed by cutting a circular flat brass box into quarters, and then slightly separating them. The opposite quadrants are placed in metallic connexion.

The electricity of the atmosphere is collected by means of Sir William Thomson's water-dropping apparatus. For this purpose a rectangular eistern of copper, capable of holding above 30 gallons of water, is placed near the ceiling on the west side of the south arm of the Upper Magnet Room. The cistern was in the first instance insulated by means of plain ebonite pillars, but this was found not to be sufficiently satisfactory, and in January of the year 1879 pillars of glass, each one encircled and nearly completely inclosed by a glass vessel containing sulphuric acid, were substituted with excellent effect. A pipe passes out from the cistern through the south face of the building, and extends about six feet into the atmosphere, the nozzle from which the water flows being about ten feet above the ground. The water in the cistern is filled up two or three times each day, so that a good and nearly constant water pressure is maintained: it passes from the end of the pipe into the atmosphere through a very small hole, and immediately breaks into drops. A wire leads from the cistern to one of the pairs of electrometer-quadrants already described, the other pair of quadrants being placed in connexion with earth. The water breaking into drops brings the cistern into the same electrical potential as that point of the atmosphere, and this potential is communicated to the pair of quadrants in connexion therewith. The varying potential of the atmosphere thus influences the motions of the within-contained needle, causing it to be deflected from zero in one direction or the other, according as the atmospheric potential is greater or less than that of the earth, that is according as it is positive or negative as respects that of the earth.

The small mirror carried by the needle, as before described, is used for the purpose of obtaining photographic record of the motions of the needle. The light of a gas-lamp falling through a slit upon the mirror is thence reflected, and by means of a plano-convex cylindrical lens is brought to a focus at the surface of a cylinder turned by clock-work, and on which is placed a properly sensitized sheet of paper. Originally one sheet contained the record for 48 hours, but in March of the year 1879 the time of revolution of the cylinder was changed in order to obtain a more extended time scale, which was made equal to that of the two anemometers, each sheet then containing the record for 24 hours only, as is the case with all the other registers. The motion of the beam of light being horizontal, the axis of the registering cylinder is also horizontal. A second fixed mirror, by means of the same gas-lamp, causes an invariable reference line to be traced round the cylinder. The actual zero is frequently determined by cutting off communication with the cistern and placing the pairs of quadrants in metallic connexion by means of a small commutator. At each hour the driving-clock shuts off the light from the cylindrical lens for a few minutes, thereby interrupting the trace and giving a time scale. An assistant also occasionally interrupts the light at arbitrary times, as described at page xviii, for the other photographic registers.

The instrument was brought into a state in which eye observations could be regularly made on 1878, July 12, and the arrangements for photographic registration were

complete in August 1878. But the insulation was frequently defective until the establishment of the sulphuric acid insulators at the beginning of the year 1879, as before mentioned. Commencing with 1879, February 8, the records were, however, quite satisfactory.

In regard to the treatment of the photographic curves, a pencil line was first drawn, representing the general form of the curve, in the same way as for the magnetic registers (page xlir). Then using a scale of inches, and calling the zero 10·00 (to avoid negative values), the hourly ordinates were measured and entered into a form, in the same way as described for the magnetic ordinates, so that mean daily values, and also mean values at every hour in each month could be determined. The values so found are contained in the tables on pages (lxiii) and (lxiv), and it will be understood that they are simply comparative. All days on which the photographs are good are included, no days being omitted on account of unusual electrical disturbance, it having been found difficult to decide on any limit beyond which it would seem proper to reject the results. It is, however, proposed, at a future time, to consider separately the more disturbed days in relation to other meteorological elements, taking for discussion together the days selected from several years.

During the autumn some inconvenience was caused by cobwebs making connexion between the cistern or its pipe and the walls of the building, and in the month of December there were interruptions owing to the freezing of the water in the exit pipe.

§ 24. Instrument for the Registration of Synshine.

The instrument with which the record of duration of sunshine is obtained is one contrived by J. F. Campbell, Esq., and kindly placed by him at the service of the Royal Observatory. It consists of a very accurately formed sphere of glass, nearly 4 inches in diameter, supported concentrically within a well turned hemispherical metal bowl in such a manner that the image of the sun, formed when the sun shines, falls always on the concave surface of the bowl. A strip of some suitable material being fixed in the bowl, the sun, when shining, burns away the material at the points at which the image successively falls, by which means the record of periods of sunshine is obtained. The strip is removed after sunset, and a new one fixed ready for the following day. The material used is blackened millboard. The register is frequently much interrupted, continuous sunshine through a whole day being a comparatively rare circumstance. The place of the meridian is marked on the strip before removing it from the bowl. A series of time scales, suitable for different periods of the year, having been prepared, the proper scale is selected and placed against the record, which is then easily transferred to a sheet of paper specially

REGISTRATION OF SUNSHINE; OZONOMETER; RESULTS OF METEOROLOGICAL OBSERVATIONS.

lxvii

ruled with equal vertical spaces to represent hours, each sheet containing the record for one calendar month. The daily sums and sums during each hour (reckoning from apparent noon) through the month are thus readily formed. The instrument gives fairly the duration of sunshine, but (usually) no register is obtained at altitudes of less than 5°. Indeed, on fine days the register, which usually has a certain breadth, tapers off in the early morning and late evening hours to a fine point, thus showing the extent to which registration under the best circumstances is effective. The recorded durations are to be understood as indicating the amount of bright sunshine, no register being obtained when the sun shines faintly (re- 1 recombined) through fog or cloud, In January of the year 1878 degrees of azimuth and Organ, harmy altitude were engraved on the metal bowl to facilitate adjustment of the recording strip. The instrument is placed on a table upon the platform above the Magnetic Zeru desamo House.

§ 25. Ozonometer.

The Ozonometer (furnished by Messrs. Horne and Thornthwaite) is fixed on the south-west corner of the roof of the Photographic Thermometer shed, at a height of about 10 feet from the ground. The box in which the papers are exposed is of wood: it is about 8 inches square, and blackened inside, and so constructed that there is free circulation of air through the box, without exposure of the paper to light. The papers are exposed and collected at 21h, 3h, and 9h, and the degree of tint produced is compared with a scale of graduated tints, numbered from 0 to 10. The value of ozone for the civil day is determined by taking the degree of tint obtained at each hour of collection as proportional to the period of exposure. Thus to form the values for any given civil day, three-fourths of the value registered at 21h, the values registered at 3h and 9h, and one-fourth of that registered at the following 21h, are added together, the resulting sum (which appears in the tables of "Daily Results") being taken as the value referring to the civil day. The mean of the 21h, 3h, and 9h values, as observed, are also given for each month in the foot notes.

§ 26. Explanation of the Tables of Results of the Meteorological Observations.

The results contained in this section refer generally to the civil day commencing at midnight.

All results throughout the section, so far as relates to the Barometer, and the Temperature of the Air and Evaporation, and to deductions made therefrom (excepting observations of maximum and minimum temperature), are founded upon the photographic records. The form into which the readings from the photographic sheets were first entered is one having a double argument, the horizontal argument ranging through the 24 hours of the civil day, and the vertical argument through the days of a calendar month. The means of the numbers standing in the vertical columns being then taken, we obtain the mean monthly photographic values of the particular element at each hour of the day, the means of the numbers in the horizontal columns giving the mean daily value. To correct the values for instrumental error it is to be remarked that the standard barometer and the standard dry-bulb and wet-bulb thermometers of the Observatory are read by eye at 21h, 0h, 3h, and 9h of every day, except on Sundays and a few other days. The comparison of these readings (corrected for temperature in the case of the barometer) with the corresponding readings from the photographs, gives the correction applicable to the photographic readings at those hours. The mean correction at each of these hours being taken through a month, corrections are interpolated for the intermediate hours, which being applied to the corresponding means of the photographic readings, the true value at each hour is obtained. The mean of the twenty-four hourly corrections in each month is adopted as the correction applicable to each mean daily value in the month. Thus mean hourly and mean daily values for the several elements are in each month obtained.

Considering the construction of the photographic barometer (already described), and having regard to the circumstance that the basement temperature is maintained so nearly uniform, the effect produced on the photographic record by changes of temperature is very small, so that the corrections can, without sensible error, be grouped by months in the way described. As regards the dry-bulb and wet-bulb thermometers, the process of correction is equivalent to giving the photographic indications in terms of the standard dry-bulb and wet-bulb thermometers exposed on the free stand.

The mean daily values of the barometer, and of the dry-bulb and wet-bulb thermometers, giving air and evaporation temperatures, found in the way described, are those inserted in the "Daily Results of the Meteorological Observations." The mean hourly values are given in following tables (pages (lii) and (liii)).

From the mean daily temperatures of the air and of evaporation are deduced, by use of Glaisher's Hygrometrical Tables, the mean daily temperature of the dew-point and degree of humidity. The factors used for calculating the dew-point given in these tables were found by Mr. Glaisher from the comparison of a great number of dew-point determinations, obtained by use of Daniell's hygrometer, with simultaneous observations of dry-bulb and wet-bulb thermometers. The first part of this investigation was published in full, in the volume of Magnetical and Meteorological Observations for 1844, pages 67-72; it was based upon all the observations made up to that time. Subsequently, the comparison was extended to include all the simultaneous observations of these instruments made at the Royal Observatory, Greenwich, from 1841

to 1854, with some observations taken at high temperatures in India, and others at low and medium temperatures at Toronto. The results at the same temperature were found to be the same at these different localities, so far as the climatic circumstances permitted comparison.

The following table exhibits the result of the entire comparison.

Table of Factors by which the Difference of Readings of the Dry-Bule and Wet-Bule Thermometers is to be Multiplied in order to produce the Difference between the Readings of the Dry-Bule and Dew-Point Thermometers.

Reading of Dry-bulb Thermometer.	Factor.	Reading of Dry-bulb Thermometer.	Factor.	Reading of Dry-bulb Thermometer.	Factor.	Reading of Dry-bulb Thermometer.	Factor.

In the same way the mean hourly values of the dew-point and degree of humidity in each month (pages (liii) and (liv)) have been calculated from the corresponding mean hourly values of air and evaporation temperatures (pages (lii) and (liii)).

The excess of the mean temperature of the air on each day above the average of 20 years, given in the "Daily Results," is found by comparing the numbers contained in column 6 with a table of average daily temperatures found by smoothing the numbers given in Table LXXVII. of the "Reduction of Greenwich Meteorological Observations, 1847–1873," which are similarly deduced from photographic records. The smoothed numbers are given in the following table.

SMOOTHED VALUES of the MEAN TEMPERATURE of the AIR as deduced from TWENTY-FOUR HOURLY Readings on each Day for every Day of the Year as obtained from the Photographic Records for the Period 1849-1868.

Day of the Month.	Јаппагу.	February.	March.	April.	May.	June.	July.	Augnst.	September.	October.	November.	December.

The daily register of rain contained in column 20 is that recorded by the gauge No. 7, whose receiving surface is 5 inches above the ground. This gange is usually read at 21h and 9h. The continuous record of Osler's self-registering gauge shows whether the amounts measured at 21h are to be placed to the same, or to the preceding civil day; and in cases in which rain fell both before and after midnight. also gives the means of ascertaining the proper proportion of the 21th amount which should be placed to each civil day. The number of days of rain given in the foot notes and in the abstract tables, pages (li) and (lxv), is formed from the records of this gauge. In this numeration only those days are counted on which the fall amounted to or exceeded 0ⁱⁿ·005.

The indications of electricity are derived from Thomson's Electrometer (described in § 23). On some days, not necessary to be specified, during interruption or failure of photographic registration, the results depend on eye observations.

No particular explanation of the anemometric results seems necessary. It may be understood generally that the greatest pressures usually occur in gusts of short duration.

For understanding the divisions of time under the headings "Clouds and Weather" and "Electricity," the following remarks are necessary:—In regard to Clouds and Weather, the day is divided by columns into two parts (from midnight to noon, and from noon to midnight), and each of these parts is subdivided into two or three parts by colons (:). Thus, when there is a single colon in the first column, it denotes that the remarks before it apply (roughly) to the interval from midnight to 6 a.m., and those following it to the interval from 6 a.m. to noon. When there are two colons in the first column, it is to be understood that the twelve hours are divided into three nearly equal parts of four hours each. And similarly for the second column. In regard to Electricity the results are included in one column; in this case the colons divide the whole period of 24 hours (midnight to midnight).

The notation employed for Clouds and Weather is as follows, it being understood that for clouds Howard's Nomenclature is used. The figure denotes the proportion of sky covered by cloud, the whole sky being represented by 10.

a	lenotes	aurora borealis	h	denotes	haze
ci	•••	cirrus	slt-h	•••	slight haze

The following is the notation employed for Electricity:-

Νó	lenote	s negative	w e	lenote	es weak
P		positive	s		strong
m		moderate	v		variable

The duplication of the letter denotes an intensity of the modification described. thus, s s, is very strong; v v, very variable. In a few cases 0 indicates no electricity, and a dash "—" accidental failure of the apparatus.

The remaining columns in the tables of "Daily Results" seem to require no special remark; all necessary explanation regarding the results therein contained will be found in the notes at the foot of the left-hand page, or in the descriptions of the several instruments given in preceding sections.

In regard to the comparisons of the extremes and means, &c. of meteorological elements with average values contained in the foot notes, it may be mentioned that the photographic barometric results are compared with the corresponding barometric results, 1854–1873, and the photographic thermometric results and deductions therefrom with the corresponding thermometric results, 1849–1868 (see "Reduction of Greenwich Meteorological Observations 1847–1873"). Other deductions, from eye observations, are compared with averages for the period 1841–1878.

The tables of Meteorological Abstracts, following the Tables of "Daily Results," require in general no special explanation. The mean amount of cloud, page (li), is the mean found from observations made usually at 21^h, 0^h, 3^h, and 9^h of each day.

It may be pointed out that the monthly means for Barometer, and Temperature of Air and Evaporation, contained in the tables referring to diurnal inequality, pages (lii) and (liii), do not, in some cases, agree with the true monthly means given in the "Daily Results," pages (xxiv) to (xlvi), and in the table on page (li), in consequence of occasional failure or interruption of the photographic process. They are, however, the proper means to be used in connexion with the numbers standing in each case immediately above them, for formation of the actual diurnal inequality. The "Number of Days employed" indicates the months in which any days are thus deficient.

§ 27. Observations of Luminous Meteors.

In arranging for the observations of meteors, the directions circulated by the Committee of the British Association have received careful attention. On the nights specially mentioned in the directions systematic watch has been kept whenever the weather was sufficiently favourable. These nights are, January 2, and 15 to 19; February 10 and 19; March 1 to 4 and 18; April 20, and 25 to 30; May 18; June 6 and 20; July 17, 20, and 29; August 3 and 7 to 13 (especially August 10); September 10; October 1 to 6 and 16 to 23; November 12 to 14, 19, 28, and 30; December 6 to 14 (especially December 11) and December 24.

Special arrangements were made in the August and November periods for observing through the night, two observers being usually charged with the observations at these times, so that observations of all meteors that should present themselves might be secured.

The observers in the year 1879 were Mr. Ellis, Mr. Nash, Mr. Greengrass, Mr. Hugo, Mr. Simmons, and Mr. A. Pead. Their observations are distinguished by the initials E., N., G., H., S., and P., respectively.

§ 28. Details of the Chemical Operations for the Photographic Records.

The paper used in 1879 was that known as Whatman's royal, a paper not specially prepared for photographic purposes.

First Operation.—Preliminary Preparation of the Paper.

The chemical solutions used in this process are the following:—

(1.) Sixteen grains of Iodide of Potassium are dissolved in one ounce of distilled water.

laxiv Introduction to Greenwich Meteorological Observations, 1879.

- (2.) Twenty-four grains of Bromide of Potassium are dissolved in one ounce of distilled water.
- (3.) When the crystals are dissolved, the two solutions are mixed together, forming the bromo-iodising solution. The mixture will keep through any length of time. Immediately before use, it is filtered through filtering paper.

A quantity of the paper, sufficient for the consumption of several weeks, is treated in the following manner, sheet after sheet.

The sheet of paper is pinned by its four corners to a horizontal board. Upon the paper, a sufficient quantity (about 50 minims, or $\frac{5}{48}$ of an onnce troy) of the bromo-iodising solution is applied, by pouring it upon the paper in front of a glass rod, which is then moved to and fro till the whole surface is uniformly wetted by the solution. Or, the solution may be evenly distributed by means of a camel-hair brush.

The paper thus prepared is allowed to remain in a horizontal position for a few minutes, and is then hung up to dry in the air; when dry, it is placed in a drawer, and may be kept through any length of time.

Second Operation.—Rendering the Paper sensitive to the Action of Light.

A solution of Nitrate of Silver is prepared by dissolving 50 grains of crystallized Nitrate of Silver in one ounce of distilled water. Since the magnetic basement has been used for photography, 15 minims of Acetic Acid have always been added to the solution.

Then the following operation is performed in a room illuminated by yellow light.

The paper is pinned upon a board somewhat smaller than itself, and by means of a glass rod its surface is wetted with 70 minims of the Nitrate of Silver solution. It is allowed to remain a short time in a horizontal position, and, if any part of the paper still shines from the presence of a part of the solution unabsorbed into its texture, the superfluous fluid is taken off by the application of blotting paper.

The paper, still damp, is immediately placed upon the cylinder, and is covered by the exterior glass tube, and the cylinder is mounted upon the revolving apparatus, to receive the spot of light formed by the mirror, which is carried by the magnet; or to receive the line of light passing through the thermometer tube.

Third Operation.—Development of the Photographic Trace.

When the paper is removed from the cylinder, it is placed as before upon a board, and a saturated solution of Gallie Acid, to which a few drops of Aceto-Nitrate of Silver are occasionally added, is spread over the paper by means of a glass rod, and

this action is continued until the trace is fully developed. The solutions are kept in the magnetic basement, and are always used at the temperature of that room. When the trace is well developed, the paper is placed in a vessel with water, and repeatedly washed with several changes of water; a brush being passed lightly over both sides of the paper to remove any crystalline deposit.

Fourth Operation.—Fixing the Photographic Trace.

The Photograph is placed in a solution of Hyposulphite of Soda, made by dissolving four or five ounces of the Hyposulphite in a pint of water; it is plunged completely in the liquid, and allowed to remain from one to two hours, until the yellow tint of the Iodide of Silver is removed. After this the sheet is washed repeatedly with water, allowed to remain immersed in water for 24 hours, and afterwards placed within folds of cotton cloths till nearly dry. Finally it is either ironed, or placed between sheets of blotting-paper and pressed.

§ 29. Personal Establishment.

The personal establishment during the year 1879 has consisted of William Ellis, Esq., Superintendent of the Magnetical and Meteorological Department, and William Carpenter Nash, Esq., Assistant.

Three or four computers have usually been attached to the Department.

Royal Observatory, Greenwich, 1880, December 13.

The unit adopted in column 3 is the Millimètre-Milligramme-Second Unit. To express the forces on the Centimètre-Gramme-Second (C.G.S.) system, the numbers must be divided by 10, equivalent to shifting the decimal point one step towards the left.

Table IV.—Mean Horizontal Magnetic Force, expressed in terms of the Mean Horizontal Force for the Year, and diminished by a Constant (o'86000 nearly), uncorrected for Temperature, on each Astronomical Day; as deduced from the Mean of Twenty-four Hourly Measures of Ordinates of the Photographic Register on that Day.

The unit adopted in column 3 is the Millimètre-Milligramme-Second Unit. To express the forces on the Centimètre-Gramme-Second (C.G.S.) system, the numbers must be divided by 10, equivalent to shifting the decimal point one step towards the left.

The value o 86000 of Horizontal Force corresponds to 1.55058 of Gauss's Unit on the Metrical (Millimètre-Milligramme-Second) system, and to

o'15506 on the C.G.S. system.

Table IX.—Mean Vertical Magnetic Force, expressed in terms of the Mean Vertical Force for the Year, and diminished by a Constant (0.96000 nearly), uncorrected for Temperature, on each Astronomical Day; as deduced from the Mean of TWENTY-FOUR HOURLY MEASURES of ORDINATES of the PHOTOGRAPHIC REGISTER on that DAY.

The unit adopted in column 3 is the Millimètre-Milligramme-Second Unit. To express the forces on the Centimètre-Gramme-Second (C.G.S.) system, the numbers must be divided by 10, equivalent to shifting the decimal point one step towards the left.

The value 0.96000 of Vertical Force corresponds to 4.20261 of Gauss's Unit on the Metrical (Millimètre-Milligramme-Second) system, and to 0.42026 on the C.G.S. system.

Table XIV.—Mean, through the Range of Months, of the Montilly Mean Determinations of the Diurnal Inequalities of Declination, Horizontal Force, and Vertical Force, for the Year 1879.

(The Results for Horizontal Force and Vertical Force are not corrected for Temperature.)

January to December.

Hour, Greenwich Mean Solar Time.	Inequality of Declination.	Equivalent in terms of Gauss's Unit measured on the Metrical System.	Inequality of Horizontal Force.	Equivalent in terms of Gauss's Unit measured on the Metrical System.	Inequality of Vertical Force.	Equivalent in terms of Gauss's Unit measured on the Metrical System.

For this table the monthly means have been formed without reference to the hour at which the observation was made on each day. In combining the monthly results, to form the annual means, weights have been given proportional to the number of observations. YEARLY MEANS of MAGNETIC DIPS for each of the NEEDLES, and GENERAL MEAN for the Year 1879.

The position of the Deflecting Magnet with regard to the suspended Magnet is always that which was formerly termed "Lateral." The Deflecting Magnet is placed on the East side of the suspended Magnet, with its markel pole alternately E, and W, and it is placed on the West side with its pole alternately E, and W, and the deflection it the table above is the mean of the four deflections observed in those positions of the magnets.

The lengths of 1 toot and 113 boot correspond to 704.8 and 396.2 millimitres respectively.

The initials E and N are those of Mr. Ellis and Mr. Nash.

P. the following calculations every observation is reduced to the temperature 35 .

The value of X in column 10 is referred to the unit Foot-Grain-Second, and that in column 11 to the unit Millimètre-Milligramme-Second. To obtain X in the Centimètre-Gramme-Second (C.G.S.) unit, the value given in column 11 must be divided by 10, equivalent to shifting the decimal point one step towards the left.

The results apply to the civil day, excepting those in Columns 16 and 17, which refer to the 24 hours ending 9h a.m. of the day against which the readings are placed,

The mean reading of the Barometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8) are deduced from the photographic records. The mean reading of the Darometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8) are deduced from the photographic records. The average temperature (Column 7) is that determined from the reduction of the photographic records from (849) to 1808. The temperature of the Dew Point (Column 9) and the Degree of Humidity (Column 13) are deduced from the corresponding temperatures of the Air and Evaporation by means of Glaisher's Hygrometrical Tables. The mean difference between the Air and Dew Point Temperatures (Column 10) is the difference between the numbers in Columns 6 and 9, and the Greatest and Least Differences (Columns 11 and 12) are deduced from the 24 hourly photographic measures of the Dry-bulb and Wet-bulb Thermometers. The results on January 8 for the Barometer, and 5 for Air Temperature, and on January 5 for Evaporation Temperature, depend partly on values inferred from eye-observations, and those from January 1 to 4 for the Barometer, and from January 5 for Air and Evaporation Temperatures, are deduced entirely from eye-observations, on account of accidental loss of roboterable resister. of aecidental loss of photographic register,

The values given in Columns 3, 4, 5, 14, 15, (6, and 17 are derived from eye-readings of self-registering thermometers.

The Electrical Apparatus was not in action throughout the month,

The mean reading of the Barometer for the month was 29 to 853, being oth 124 higher than the average for the 20 years, 1854-1873.

TEMPERATURE OF THE AIR.

The highest in the month was 50 '5 on January 1; the lowest in the month was 19 '4 on January 12; and the range was 3121.

The mean of all the highest daily readings in the month was 35 +1, being 8 +5 lower than the average for the 38 years, 1841-1878. The mean of all the lowest daily readings in the month was 38%, being 5% forcer than the average for the 38 years, 1841-1878. The mean daily range was 7%, being 2% 6 hes than the average for the 38 years, 1841-1878.

The mean for the month was 31° 8, being 6° 9 lower than the average for the 20 years, 1849-1868

The mean Temperature of Evaporation for the month was 30 17, being 6 17 lower than

the average for the 20 years, 1849-1868.

The mean Temperature of the Dew Point for the month was 27 1, being 8 3 lower than

The mean Degree of Humidity for the month was \$2.5, being 4.8 less than

The mean Elastic Force of Vapour for the month was o'n 148, being o'n 059 less than

The mean Weight of Vapour in a Cubic Foot of Air for the month was 1er. 8, being of 6 less than

The mean Weight of a Cubic Foot of Air for the month was 563 grains, being 11 grains greater than

The mean amount of Cloud for the month (a clear sky being represented by o and an overcast sky by 10) was 7.8.

The mean proportion of Sanshine for the month (constant sunshine being represented by 1) was 0.06. The maximum daily amount of Sanshine was 4.4 hours on January 10. The highest reading of the Solar Radiation Thermometer was 63.8 on January 15; and the lowest reading of the Terrestrial Radiation Thermometer was 18.7 on January 11.

The mean daily distribution of Ozone was, for the 12 hours ending 9 n.m., 2:1: for the 6 hours ending 3 p.m., 0:2; and for the 6 hours ending 9 p.m., 0:2.

The Proportions of Wind referred to the cardinal points were N. 6, E. 15, S. 5, and W. 4. One day was calm.

The Greatest Pressure of the Wood in the month was 19 to 5 on the square foot on January 1. The mean daily Horizontal Movement of the Air for the month was 283 miles; the greatest daily value was 576 miles on January 8; and the least daily value 35 miles on January 6.

Rain fell on 12 days in the month, amounting to 2'n 586, as measured in the simple cylinder gauge partly sunk below the ground; being o'n 480 greater than the average fall for the 38 years, 1841-1878.

The results apply to the civil day, excepting those in Columns 16 and 17, which refer to the 24 hours ending 9 a.m. of the day against which the readings are placed.

The mean reading of the Barometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8) are deduced from the photographic records. The The mean reading of the Barometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8) are deduced from the photographic records iron 1849 of 1868. The temperature of the Dev Point (Column 9) and the Degree of Hamidity (Column 13) are deduced from the corresponding temperatures of the Air and Evaporation by means of Glaishor's Hygrometrical Tables. The mean difference between the Air and Dew Point Temperatures (Column 10) is the difference between the numbers in Columns 6 and 9, and the Greatest and Least Differences (Columns 11 and 12) are deduced from the 24 hourly photographic measures (1 the Try-bulb and Wet-bulb Thermometers. The results on February 21 and 25 for Air Temperature, and on February 21, 225, and 26 for Evaporation Temperature, depend partly on values inferred from eye-observations, and those from February 1 to 12 for Air and Evaporation Temperatures, are deduced entirely from eye-observations, on account of accidental loss of photographic register.

The values given in Columns 5, 4, 5, 14, 15, 16, and 17 are derived from eye-readings of self-registering the immenters.

The Electrical Apparatus was not in action from February 1 to 8.

The mean reading of the Barometer for the month was $29^{\pm i}369$, being $0^{\circ}463$ for r than the average of the 20 years, 1834 ± 1873 .

The highest in the month was \$2.18 or Tebruary 9; the lowest in the month was \$24.15 on Tebruary 22 and \$24.1 and the range was \$28.13.

The mean of all the highest daily readings in the month was 42 %, being 2 % lower than tie average for the 38 years, 1841-1878.

The mean of all the lowest daily readings in the month was 34 13, being the same as the average for the 38 years, 184 - 1878.

The mean daily range was 8 +3, being 2 +9 has than the average for the 38 years, 1841-1878.

The mean for the month was 38 13, being 1 14 lower than the average for the 20 years, 1849-1868.

The mean Temperature of Evaporation for the month was 3700, being 0 9 lower than

The mean Temperature of the Dem Point for the month was 34 .8, being 0 .6 force than

The mean Degree of Humiditu for the month was 87.4, being 2.6 greater than

The mean Elastic Force of Vapour for the month was 0 "202, being 0 " 005 less than

The mean Weight of Vapour in a Cubic Foot of Air for the month was 2000 4, being the same as

The mean Weight of a Cubic Foot of Air for the month was 547 grains, being 7 grains less than

The mean amount of Cloud for the month (a clear sky being represented by o and an overeast sky by 10) was 8.8.

The mean proportion of Sunshine for the month (constant sun-line being represented by 1) was o't1. The maximum daily amount of Sunshine was 7 1 hours on February 24. The highest reading of the Solar Radiation Thermometer was 81'4 on February 12; and the lowest reading of the Terrestrial Radiation Thermometer was 23'0 on February 24.

the average for the 20 years, 1849-1868.

The mean daily distribution of Ozone was, for the 12 hours ending 9 a.m., 2.2: for the 6 hours ending 3 p.m., 0.2; and for the 6 hours ending 9 p.m., 0.6.

The Proportions of Wood referred to the cardinal points were N. 6, E. 7, S. 8, and W. 7.

The Greatest Pressure of the Wind in the month was 8000 on the square foot on February 7. The mean daily Horizontal Movement of the Air for the month was 303 miles; the greatest daily value was 606 miles on February 7; and the least daily value 94 miles on February 22.

Rain fell on 21 days in the month, amounting to 3 most 5, as measured in the simple cylinder gauge partly sunk below the ground; being 2 most 433 greater than the average fall for the 38 years, 1841-1878.

The results apply to the civil day, excepting those in Columns 16 and 17, which refer to the 24 hours ending 9° a.m. of the day against which the readings are placed.

The mean reading of the Errometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8) are deduced from the photographic records. The average temperature (Column 5) is that determined from the reduction of the photographic records from 1849 to 1868. The temperature of the Dew Point (Column 9) and the Degree of Humidity (Column 13) are deduced from the corresponding temperatures of the Air and Evaporation by means of Glaisher's Hygrometrical Tables. The mean difference between the Air and Dew Point Temperatures (Column 10) is the difference between the numbers in Columns 6 and 9, and the Greatest and Least Differences (Column 11) and 12) are deduced from the 24 hourly photographic measures of the Dry Judb and Wet-Judb Thermometers. The results on March 21 and 22 for Air Temperature; and on March 22 for Evaporation Temperature, depend partly on values inferred from eye-observations, on account of accidental loss of obstance-order registers. photographic register.

The values given in Columns 3, 4, 5, 14, 15, 16, and 17 are derived from eye-readings of self-registering thermometers.

The Electrical Apparatus was not in action from March 17 to 21.

The mean reading of the Barometer for the menth was 29% 808, being o cast higher than the average for the 20 years, (854-1877).

Temperature of the $\Lambda_{\rm BR}$

The highest in the month was 63% on March 19% the lowest in the month was 28% on March 8% and the range was 33%. The mean of all the highest daily readings in the month was 49%, being 0% lower than the average for the 38% years, 18%

The mean of all the lowest daily readings in the month was 44 %, being 0 4 lower than the average for the 38 years, 1841-1878.

The mean daily range was 14 *2, being 0 *4 losy than the average for the 38 years, 1841-1878.

The mean for the month was 41 '2, being 0 '3 lower than the average for the 20 years, 1849-1868

The mean Temperature of Evaporation for the month was 38 .8, being 0 .2 lower than

The mean Temperature of the Dew Point for the month was 35 . 6, being o .4 lower than

The mean Degree of Humidity for the month was 80.6, being 0.3 less than

The mean Elastic Force of Vapour for the month was o 1208, being on 1004 less than

The mean Weight of Vapour in a Cubic Foot of Air for the month was 2500-4, being core 1 less than

The mean Weight of a Cubic Foot of Air for the month was 552 grains, being 2 grains greater than

The mean amount of Cloud for the month (a clear sky being represented by o and an overcast sky by 10) was 6.8.

The mean proportion of Sunshine for the month (constant sunshine being represented by 1) was 0°25. The maximum daily amount of Sunshine was 8°9 hours on March 6

the average for the 20 years, 1849-1868.

The highest reading of the Solar Radiation Thermometer was 104'19 on March 29; and the lowest reading of the Texrestral Radiation Thermometer was 24'19 on March 13. The mean daily distribution of Ozone was, for the 12 hours ending 9 a.m., t+4; for the 6 hours ending 3 p.m., o+7; and for the 6 hours ending 9 p.m., o+3.

The Proportions of Wind referred to the cardinal points were N. 7, E. 7, S. 8, and W. 8. One day was calm.

The Greatest Pressure of the Wind in the month was 1510 of on the square foot on March 23. The mean daily Horizontal Movement of the Air for the month was 516 miles; the greatest daily value was 591 miles on March 23; and the least daily value 114 miles on March 18.

Rain fell on 14 days in the month, amounting to on+603, as measured in the simple cylinder gauge partly sunk below the ground; being on+888 less than the average full for the 38 years, 1841-1878.

The results apply to the civil day, excepting those in Columns (6 and (7), which refer to the 24 hours ending 9 a.m. of the day against which the readings are placed.

The values given in Columns 3, 4, 5, (4, 15, 16, and 17 are derived from eye-readings of self-registering thermometers.

The mean reading of the Baromiter for the mouth was 29" 519, being o" 284 lower than the average for the 20 years, 1854-1873.

The mean reading of the Barometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8) are deduced from the photographic records. The average temperature (Column 7) is that determined from the reduction of the photographic records from 1849 to 1868. The temperature of the Dew Point (Column 4) and the Degree of Humidity (Column 13) are deduced from the corresponding temperatures of the Air and Evaporation by means of Glaisher's Hygrometrical Tables. The mean difference between the Air and Dew Point Temperatures (Column 10) is the difference between the numbers in Columns 6 and 9, and the Greatest and Least Differences (Columns 11 and 12) are deduced from the 24 hourly photographic measures of the Diy-bulb and Wet-bulb Thermometers. The results on April 29 for Air Temperature, and on April 11 and 29 for Evaporation Temperature, depend partly on values inferred from eye-observations, on account of accidental loss of photographic register.

The highest in the month was 65 °8 on April 26; the lowest in the month was 27 °7 on April (2); and the range was 33 °4. The mean of all the highest duly readings in the month was 32 °6, being 3 °2 lower than the average for the 38 years, 4841-4878. The mean of all the lowest duly readings in the month was 32 °6, 3, being 3 °2 lower than the average for the 28 years, 4841-4878.

The mean daily range was 16/3, being 2/2 less than the average for the 38 years, 1841-1878. The mean for the month was 43/5, being 4/0 lower than the average for the 20 years, 1849-1868.

Number of Jolumn for Reference.	23	2.4	25	26	27	28		29	30

The mean Temperature of Evaporation for the month was 40° 8, being 3° 1 lower than

The mean Temperature of the Dew Point for the month was 37 '6, being 20 7 lower than

The mean Degree of Humulity for the month was 80'1, being 3'2 greater than

The mean Elastic Force of Vapour for the month was o'n 225, being o'n 025 less than

The mean Weight of Vapour in a Cubic Foot of Air for the month was 2008 6, being 080 3 less than

The mean Weight of a Cubic Foot of Air for the month was 544 grains, being the same as

The mean amount of Cloud for the month (a clear sky being represented by o and an overcast sky by 10) was 7.9.

The mean proportion of Sanshine for the mouth (constant sunshine being represented by 1) was 0 18. The maximum daily amount of Sanshine was 9 3 hours on April 4.

the average for the 20 years, 1849-1868.

The highest reading of the Solar Radiation Thermometer was 130 1 on April 26; and the lowest reading of the Terrestrial Radiation Thermometer was 24 0 on April 12.

The mean daily distribution of Ozone was, for the 12 hours ending 9 a.m., 2.4; for the 6 hours ending 3 p.m., 1.1; and for the 6 hours ending 9 p.m., 0.8.

The Proportions of Wind referred to the cardinal points were N. 9, E. 7, S. 9, and W. 5.

The Greatest Pressure of the Wind in the mouth was 8th 5 on the square foot on April 6. The mean daily Horizontal Movement of the Air for the month was 229 miles; the greatest daily value was 528 miles on April 11; and the least daily value 111 miles on April 22.

Rain fell on t6 days in the month, amounting to 2" 1599, as measured in the simple cylinder gauge partly sunk below the ground; being of 962 greater than the average fall for the 38 years, 1841-1878.

The results apply to the civil day, excepting those in Columns 16 and 17, which refer to the 24 hours ending 9 a.m. of the day against which the readings are placed.

The mean reading of the Barometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8) are deduced from the photographic records. The average temperature (Column 7) is that determined from the reduction of the photographic records from 1849 to 1868. The temperature of the Dev Point (Column 9) and the Decree of Hamility (Column 13) are deduced from the corresponding temperatures of the Air and Evaporation by means of Glaisher's Hygrometrical Tables. The mean difference between the Air and Dev Point Temperatures (Column 10) is the difference between the numbers in Columns 6 and 9, and the Greatest and Least Differences (Columns 11 and 12) are deduced from the 24 hourly photographic measures of the Dry-bulb and Wet-bulb Thermometers.

The values given in Columns 3, 4, 5, 14, 15, 16, and 17 are derived from eye-readings of self-registering thermometers.

The mean reading of the Barometer for the month was 29" 833, being on os 6 higher than the average for the 20 years, 1854-1873.

Temperature of the Air.

The highest in the month was 70°6 on May 21; the lowest in the month was 35°0 on May 10; and the range was 40°6. The mean of all the highest daily readings in the month was 58°4, being 5°9 lower than the average for the 38 years, 1841-1878. The mean of all the lewest daily readings in the month was 40°1, being 3°8 lower that average for the 38 years, 1841-1878. The mean daily range was 18°3, being 2°1 less than the average for the 38 years, 1841-1878.

The mean for the month was 48 . 6, being 4 . 5 lower than the average for the 20 years, 1849-1868.

The mean Temperature of Evaporation for the month was 44° 8, being 4 '1 lower than

The mean Temperature of the Dew Point for the month was 40° 6, being 4° 5 lower than The mean Degree of Humidity for the month was 74.1, being 1.3 less than

The mean Elastic Force of Vapour for the month was o'n 253, being o'n 048 less than

The mean Weight of Vapour in a Cubic Foot of Air for the month was 22th, 9, being 05t 5 less than

The mean Weight of a Culuc Foot of Air for the month was 544 grains, being 6 grains greater than

The mean amount of Cloud for the month (a clear sky being represented by o and an overcast sky by 10) was 7.0.

The mean proportion of Sunshine for the month (constant sunshine being represented by 1) was 0 28. The maximum daily amount of Sunshine was 12 8 hours on May 4. The highest reading of the Solar Radiation Thermometer was 142 3 on May 20; and the lowest reading of the Terrestrial Radiation Thermometer was 24 6 on May 10. The mean daily distribution of Ozone was, for the 12 hours ending 9 a.u., 2.2; for the 6 hours ending 3 p.m., 1.6; and for the 6 hours ending 9 p.m., 0 9.

The Proportions of Wind referred to the cardinal points were N. 10, E. 5, S. 9, and W. 7.

The Greatest Pressure of the Wind in the month was 8000 on the square foot on May 15. The mean daily Horizontal Movement of the Air for the month was 260 miles; the greatest daily value was 557 miles on May 15; and the least daily value 94 miles on May 20.

the average for the 20 years, 1849-1868.

Rain fell on 15 days in the month, amounting to 3" 361, as measured in the simple cylinder gauge partly sunk below the ground; being 1" 327 or cater than the average fall for the 38 years, 1841-1878.

The results apply to the civil day, excepting those in Columns 16 and 17, which refer to the 24 hours ending 9" a.m. of the day against which the readings are placed.

The values given in Columns 3, 4, 5, 14, 15, 16, and 17 are derived from cyc-readings of self-registering thermometers.

The mean reading of the Barometer for the month was 29th 641, being 0th 187 lower than the average for the 20 years, 1854-1873.

The mean reading of the Barometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8) are deduced from the photographic records. The average temperature (Column 7) is that determined from the reduction of the photographic records from 1849 to 1868. The temperature of the Dew Point (Column 9) and the Degree of Humidity (Column 13) are deduced from the corresponding temperatures of the Air and Evaporation by means of Glaisher's Hygrometrical Tables. The mean difference between the Air and Dew Point Temperatures (Column 15) is the difference between the numbers in Columns 6 and 9, and the Greatest and Least Differences (Column 13) are deduced from the 24 hourly photographic measures of the Dry-lub and Wet-bulb Thermometers. The results on June 9 and 10 for Evaporation Temperature, depend partly on values inferred from eye-observations, on account of accidental loss of photographic register.

TEMPERATURE OF THE AIR.

The highest in the month was 72° \cdot 7 on June 14 and 28; the lowest in the month was 41° 5 on June 43 and the range was 31° 4. The mean of all the highest daily readings in the roomb was 67° \cdot 0, being 4° 2 lower than the average for the 38 years, 1841–1878. The mean of all the lowest daily readings in the month was 49° 6, being 9° 4 lower than the average for the 38 years, 1841–1878. The mean daily range was 17° 4, being 37° 8 loss than the average for the 38 years, 1841–1878. The mean for the month was 57° \cdot 0, being 2° \cdot 1 lower than the average for the 20 years, 1849–1868.

The mean Temperature of Evaporation for the month was 53 · 6, being 1° · 6 lower than

The mean Temperature of the Dem Point for the month was 500.5, being 00.7 lower than

The mean Degree of Humidity for the month was 79 o, being 5.7 greater than

The mean Elastic Force of Vapour for the month was on 367, being on one less than

The mean Weight of Vapour in a Cubic Foot of Air for the month was 4200 1, being off t less than

The mean Weight of a Cubic Foot of Air for the month was 531 grains, being the same as

The mean amount of Cloud for the month (a clear sky being represented by o and an overcast sky by 10) was 7.7.

The mean proportion of Sanshine for the month (constant sunshine being represented by 1) was 0.28. The maximum daily amount of Sanshine was 13.5 hours on June 10.

the average for the 20 years, 1849-1868.

The highest reading of the Solar Radiation Thermometer was 150° 5 on June 28; and the lowest reading of the Terrestrial Radiation Thermometer was 35° 8 on June 5.

The mean daily distribution of Ozone was, for the 12 hours ending 9 a.m., 3.5; for the 6 hours ending 3 p.m., 1.4; and for the 6 hours ending 9 p.m., 1.6.

The Proportions of Wind referred to the cardinal points were N. 1, E. 3, S. 15, and W. 10. One day was calm.

The Greatest Pressure of the Wind in the mouth was 16th 5 on the square foot on June 21. The mean daily Horizontal Movement of the Air for the mouth was 277 miles; the greatest daily value was 462 miles on June 22; and the least daily value 145 miles on June 13.

Ram fell on 20 days in the month, amounting to 4" 288, as measured in the simple cylinder gauge partly sunk below the ground; being 2" 302 greater than the average fall for the 38 years, 1841-1878.

The results apply to the civil day, excepting those in Columns 16 and 17, which refer to the 24 hours ending 9th a m, of the day against which the readings are placed.

The mean reading of the Barometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8) are deduced from the phetographic records. The average temperature (Column 7) is that determined from the reduction of the photographic records from 1849 to 1868. The temperature of the Dew Point (Column 9) and the Degree of Humidity (Column 13) are deduced from the corresponding tengeratures of the Air and Evaporation by means of Glaisher's Hygrometrical Tables.

The mean difference between the Air and Dow Point Temperatures (Column 12) is the difference between the numbers in Columns 6 and 9, and the Greatest and Least Differences (Columns 11 and 12) are deduced from the 24 hourly photographic measures of the Dry-bulb and Wet-bulb Thermometers.

The values given in Columns 3, 4, 5, 14, 15, 16, and 17 are derived from eye-readings of self-registering thermometers.

The mean reading of the Barometer for the month was 2910,629, being 000,180 lower than the average for the 20 years, 1854-1873.

Temperature of the Air.

FIGHALTHE OF THE ATE.

The highest in the month was 86° 6 on July 30°; the lowest in the month was 46°; 3 on July (1); and the range was 34°; 3.

The mean of all the highest daily readings in the month was 67°; 2, being 7°; 2 lower than the average for the 38 years, (841–1878. The mean of all the lowest daily readings in the month was 51°; 7, being 1°; 8 lower than the average for the 38 years, (841–1878. The mean daily range was 15°; 5, being 5°; 7 loss than the average for the 38 years, (844–1878. The mean for the month was 58°; 2, being 4°; 4 lower than the average for the 20 years, (849–1868.

Sumber of Column for Reference.	23	2 4	25	26	27	28		2 9	30

The mean Temperature of Evaporation for the month was 55° 3, being 2° 4 lower than

the average for the 20 years, 1849-1868.

The mean Temperature of the Dew Point for the month was 520.7, being 10.0 lower than

The mean Degree of Humidity for the month was 82.4, being 9.4 greater than

The mean Elastic Force of Vapour for the month was o'" 399, being o'" or 4 has than

The mean Weight of Vapour in a Cubic Foot of Air for the month was 45r . 4, being 08r . 2 less than

The mean Weight of a Cubic Foot of Air for the month was 529 grains, being a grain greater than

The mean amount of Cloud for the month (a clear sky being represented by o and an overcast sky by 10) was 8.5.

The mean proportion of Sunshine for the month (constant sunshine being represented by 1) was 0.20. The maximum daily amount of Sunshine was 11.1 hours on July 29.

The highest reading of the Solar Radiation Thermometer was 158 8 on July 19; and the lowest reading of the Terrestrial Radiation Thermometer was 40 0 on July 11.

The mean daily distribution of Ozone was, for the 12 hours ending 9 a.m., 2.2: for the 6 hours ending 3 p.m., 0.6; and for the 6 hours ending 9 p.m., 0.4.

The Proportions of Wind referred to the cardinal points were N. 4, E. 3, S. 10, and W. 14.

The Greatest Pressure of the Wind in the month was 22 lbs on the square foot on July 20. The mean daily Horizontal Movement of the Air for the month was 314 miles; the greatest daily value was 639 miles on July 21; and the least daily value 115 miles on July 16.

Rain fell on 19 days in the month, amounting to 3in 723, as measured in the simple cylinder gauge partly sunk below the ground; being 1in 354 greater than the average fall for the 38 years, 1841-1878.

The results apply to the civil day, excepting those in Columns 16 and 17, which refer to the 24 hours ending 9h a.m. of the day against which the readings are placed.

The mean reading of the Barometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8) are deduced from the photographic records. The average temperature (Column 7) and the mean temperatures of the Air and Evaporation (Column 6) and 8) are deduced from the photographic records from 1849 to 1858. The temperature of the Dew Point (Column 6) and the Degree of Humidity (Column 13) are deduced from the corresponding temperatures of the Air and Evaporation by means of Glaisher's Hygrometrical Tables. The mean difference between the Air and Dew Point Temperatures (Column 10) is the difference between the numbers in Columns 6 and 9, and the Greatest and Least Differences (Columns 11 and 12) are deduced from the 24 hourly photographic measures of the Dry-hulb and Wet-bulb Thermometers. The values given in Columns 3, 4, 5, 14, 15, 16, and 17 are derived from eye-readings of self-registering thermometers.

The amount of Sunshine on August 6 was in part estimated, on account of accidental loss of register.

The mean reading of the Barometer for the month was 29" 672, being o'n* 127 lower than the average for the 20 years, 1854-1873.

TEMPERATURE OF THE AIR,

The highest in the month was 79° 7 on August 15; the lowest in the month was 44° 0 on August 31; and the range was 35° 7. The mean of all the highest daily readings in the month was 69° 4, being 3° 7 lower than the average for the 38 years, 1841–1878. The mean of all the lowest daily readings in the month was 53° 0, being 0° 2 lower than the average for the 38 years, 1841–1878. The mean daily range was 16° 4, being 3° 5, less than the average for the 38 years, 1841–1878. The mean for the month was 60° 2, being 1° 7 lower than the average for the 20 years, 1849–1868.

The	mean Tennerature of	Evaporation for the	nonth	was a	721.	being o	:= lower than	٦	

The mean Temperature of Evaporation for the month was 572.4, being of 5 lower than

the average for the 20 years, 1849-1868.

The mean Temperature of the Dew Point for the month was 55°0, being o°6 higher than

The mean Degree of Humidity for the month was 83:5, being 7:0 greater than

The mean Elastic Force of Yapour for the month was o'n 433, being o'n 009 greater than

The mean Weight of Vapour in a Cubic Foot of Air for the month was 4575.8, being ost 1 greater than

The mean Weight of a Cubic Foot of Air for the month was 527 grains, being 1 grain less than

The mean amount of Cloud for the month (a clear sky being represented by o and an overcast sky by 10) was 7.2.

The mean proportion of Sunshine for the month (constant sunshine being represented by 1) was o 31. The meanimum daily amount of Sunshine was 12 1 hours on August 12. The highest reading of the Solar Radiation Thermometer was 150 0 on August 151 and the lowest reading of the Terrestrial Radiation Thermometer was 1100 on August 30

The mean daily distribution of Ozone was, for the 12 hours ending 9 a.m., 3°4; for the 6 hours ending 3 p.m., 1°2; and for the 6 hours ending 9 p.m., 1°2.

The Proportions of Wind referred to the cardinal points were N. 3, E. 4, S. 13, and W. 11.

The Greatest Pressure of the Wind in the month was 1916 on the square foot on August 27. The mean daily Horizontal Movement of the Air for the month was 285 miles; the greatest daily value was 531 miles on August 29; and the least daily value 87 miles on August 10.

Ram fell on 20 days in the month, amounting to 5 in 194, as measured in the simple cylinder gauge partly sunk below the ground; being 2 in 772 greater than the average fall for the 38 years, 1841-1878.

The results apply to the civil day, excepting those in Columns 16 and 17, which refer to the 24 hours ending 9h a.m. of the day against which the readings are placed.

The mean reading of the Barometer for the month was 29th 800, being oth or 3 higher than the average for the 20 years, 1854-1873.

The mean reading of the Larometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8) are deduced from the photographic records. The The mean reading of the Barometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8) are deduced from the photographic records. The average temperature (Column 7) is that determined from the reduction of the photographic records from 1849 to 1868. The temperature of the Dew Point (Column 9) and the Degree of Humidity (Column 13) are deduced from the corresponding temperatures of the Air and Evaporation by means of Glaisher's Hygrometrical Tables. The mean difference between the Air and Dew Point Temperatures (Column 10) is the difference between the numbers in Columns 6 and 9, and the Greatest and Least Differences (Columns 11 and 12) are deduced from the 24 hourly photographic measures of the Dry-bulb and Wet-bulb Thermometers. The result on September 28 for the Barometer, depends partly on values inferred from eye-observations, on account of accidental loss of photographic register.

The values given in Columns 3, 4, 5, 4, 5, 16, and 17 are derived from eye-readings of self-registering thermometers.

TEMPERATURE OF THE AIR.

The highest in the month was 73 '4 on September 3; the lowest in the month was 39° 5 on September 1 and 25; and the range was 33° 9.

The mean of all the highest daily readings in the month was 65 15, being 2 11 lower than the average for the 38 years, 1841-1878.

The mean of all the lowest daily readings in the month was 49° 3, being o' 2 higher than the average for the 38 years, 1841-1878.

The mean daily range was 1603, being 2012 less than the average for the 38 years, 1841-1878.

The mean for the month was 56° 3, being 1' 2 lower than the average for the 20 years, 1849-1868.

The mean Temperature of Evaporation for the month was 53° 7, being 0° 6 lower than

the average for the 20 years, 1849-1868.

The mean Temperature of the Dew Point for the month was 51 '2, being o'2 lower than

The mean Degree of Humidity for the month was 83.4, being 3.3 greater than

The mean Elastic Force of Vapour for the month was o'n 377, being o'n ooz less than

The mean Weight of Vapour in a Cubic Foot of Air for the month was 4500 2, being the same as The mean Weight of a Cubic Foot of Air for the mouth was 534 grains, being 2 grains greater than

The mean amount of Cloud for the month (a clear sky being represented by o and an overcast sky by 10) was 6.7.

The mean proportion of Sanshine for the month (constant sunshine being represented by 1) was 31. The maximum daily amount of Sanshine was 11.3 hours on September 1.

The highest reading of the Solar Radiation Thermometer was 141 4 on September 3; and the lowest reading of the Terrestrial Radiation Thermometer was 36° on

The mean daily distribution of Ozone was, for the 12 hours ending 9 a.m., 1 : 5; for the 6 hours ending 3 p.m., 0 : 8; and for the 6 hours ending 9 p.m., 0 : 4.

The Proportions of Wind referred to the cardinal points were N. 4, E. 6, S. 10, and W. 8. Two days were calm.

The Greatest Pressure of the Word in the mouth was 10 th square foot on September 9. The mean daily Harizontal Movement of the Air for the mouth was 222 miles; the greatest daily value was 486 miles on September 9; and the least daily value 47 miles on September 18.

Ratin fill on 14 days in the month, amounting to 2 in 874, as measured in the simple cylinder gauge partly sunk below the ground; being 0 in 640 greater than the average fall for the 38 years, 1841-1878.

The results apply to the civil day, excepting those in Columns 16 and 17, which refer to the 24 hours ending 91 a.m. of the day against which the readings are placed.

The mean reading of the Barometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8), are deduced from the photographic records. The average tension of the Developerature (Column 7) as that determined from the reduction of the photographic records from 1849 to 1868. The temperature of the Dev Point (Column 9) and the Degree of Humidity (Column 13) are deduced from the corresponding temperatures of the Xir and Evaporation by means of Glaisher's Hygrometrical Tables. The mean difference between the Annihors in Column 6 and 9, and the Greatest and Least Differences (Column 11) and 12) are deduced from the 24 hourly photographic measures of the Dry-builb and Wet-builb Thermometers.

The values given in Columns 3, 4, 5, 14, 15, 16, and 17 are derived from eye-readings of self-registering thermometers,

The observations of the temperature of the water of the Thames were discontinued on October 26.

The mean reading of the Barometer for the month was 2910 952, being o'e 232 higher than the average for the 20 years, 1854-1873.

The highest in the month was 67 '8 on October 4: the lowest in the month was 33 '1 on October 26; and the range was 34 '7.

The highest in the month was 67. 'S on October 44; the lowest in the month was 33. 't on occording and not compared by the month was 55. '6, being 2. '8 lower than the average for the 38 years, 1841-1878. The mean of all the lowest daily readings in the month was 43. '0, being 0. '7 lower than the average for the 38 years, 1841-1878. The mean daily range was 12. '6, being 2. '1 loss than the average for the 38 years, 1841-1878.

The mean for the month was 49 '3, being 1 '7 lower than the average for the 20 years, 1849-1868.

Number of Column for Reference.	23	24	25	26	2,	28		2 9	30

The mean Temperature of Evaporation for the month was 47 '8, being 12-1 lower than

the average for the 20 years, 1849-1868.

The mean Temperature of the Dew Point for the month was 46 2, being oo 6 lower than

The mean Degree of Humality for the month was 89.4, being 3.3 greater than

The mean Elastic Force of Vapour for the month was out 313, being o 2008 less than

The mean Weight of Vapour in a Cubic Foot of Air for the month was 3200 6, being the same as

The mean Weight of a Cubic Foot of Air for the mouth was 545 grains, being 6 grains greater than

The mean amount of Cloud for the month (a clear sky being represented by o and an overeast sky by 10) was 7.1.

The mean proportion of Sanshine for the month (constant sunshine being represented by 1) was or 21. The maximum daily amount of Sanshine was 6:7 hours on October 16. The highest reading of the Nodar Radiation Thermometer was 124 '5 on October 7; and the lowest reading of the Terrestrial Radiation Thermometer was 29 '2 on October 16.

The mean daily distribution of Ozone w.s., for the 12 hours ending 9 a.m., 0.9; for the 6 hours ending 3 p.m., 0.2; and for the 6 hours ending 9 p.m., 0 1.

The Proportions of Wind referred to the cardinal points were N. 7, E. 8, S. 6, and W. 8. Two days were calm.

The Createst Pressure of the Wind in the month was 9° 3 on the square foot on October 19. The mean daily Horizontal Meccment of the Air for the month was 253 miles; the greatest daily value was 575 miles on October 19; and the least daily value 32 miles on October 12.

Ram tell on 12 days in the month, amounting to 0 761, as measured in the simple cylinder gauge partly sunk below the ground; being 210 1111 less than the average fall for the 38 years, 1841-1878.

The results apply to the civil day,

The mean reading of the Barometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8) are deduced from the photographic records. The mean reason of a the farometer (Commu 2) and the mean 5 inperatures of the Air and Evaporation (Commu 5 6 and 8) are deduced from the pincographic records. The average temperature (Column 7) is that determined from the reduction of the photographic records from 1840 to 1868. The temperature of the Dev Point (Column 9) and the Degree of Humidity (Column 13) are deduced from the corresponding temperatures of the Air and Evaporation by means of Glaisher's Hygremetrical Tables. The mean difference between the Air and Dev Point Temperatures (Column 10) is the difference between the numbers in Columns 6 and 9, and the Greatest and Least Differences (Columns 11 and 12) are deduced from the 24 hourly photographic measures of the Dry-bailb and Wet-bulb Thermometers. The results on November 28 and 29 for the Barometer, and on November 14, 28, and 49 for Air and Evaporation Temperatures, depend partly on values inferred from eye-observations, on account of accident loss of abstract columns. of accidental less of photographic registe

The values given in Column- 3, 4, 5, 14, and 15 are derived from eye-readings of self-registering thermometers.

No observations of the temperature of the water of the Thames were made during this month,

The mean reading of the Baromotor for the month was 30000035, being 0000264 higher than the average for the 20 years, 1854-1873.

TEMPERATURE OF THE AM.

The highest in the month was \$4700 on November (8) the lowest in the month was 2100 on November (6) and the railze was 3306.

The mean of all the highest daily readings in the month was 43 + 5, bourg 5 + 3 lower than the average for the 38 years, 1841-1878. The mean of all the lowest daily readings in the month was 53 + 5, bourg 5 + 3 lower than the average for the 38 years, 1841-1878. The mean daily range was 10 + 2, bourg 1 + 3 loss than the average for the 38 years, 1841-1878.

The mean for the month was 38 '5, being 4 '2 lower than the average for the 20 years, 1849-1868.

The mean Temperature of Evaporation for the month was 37 0, being 4 2 lower than

The mean Temperature of the Dew Point for the month was 342.7, being 42.6 lower than

The mean Degree of Humidity for the month was 86.4, being 0.9 less than

The mean Elastic Force of Vapour for the mouth was o'n 201, being o'n 039 less than

The mean Weight of Vapour in a Cubic Foot of Air for the month was 2515. 4, being oct 4 less than

The mean Weight of a Cubic Foot of Air for the month was \$59 grains, being 10 grains greater than

The mean amount of Cloud for the month (a clear sky being represented by o and an overcast sky by 10) was 6.9.

The mean proportion of Sunshine for the month (constant sunshine being represented by 1) was o'16. The maximum daily amount of Sunshine was 5.3 hours on

November 18. The highest reading of the Solar Radiation Thermometer was 87 '8 on November 19; and the lowest reading of the Terrestrial Radiation Thermometer was 16 to on

the average for the 20 years, 1849-1868.

November 15. The mean daily distribution of Ozone was, for the 12 hours ending 9 a.m., o o; for the 6 hours ending 3 p.m., o o; and for the 6 hours ending 9 p.m., o to.

The Proportions of Wind referred to the cardinal points were N. 13, E. 4, S. 4, and W. 8. One day was calm.

The Greatest Pressure of the Wind in the month was 5100 4 on the square foot on November 12. The mean daily Horizontal Movement of the Air for the month was 239 miles; the greatest daily value was 597 miles on November 12; and the least daily value 87 miles on November 15.

Ram fell on 12 days in the month, amounting to oin 906, as measured in the simple cylinder gauge partly sunk below the ground; being 11 362 less than the average fall for the 38 years, 1841-1878.

The results apply to the civil day.

The mean reading of the Barometer (Column 2) and the mean temperatures of the Air and Evaporation (Columns 6 and 8) are deduced from the photographic records. The average temperature (Column 7) is that determined from the reduction of the photographic records from 1849 to 1868. The temperature of the Deep Point (Column 9) and the Deepee of Humidity (Column 4) are deduced from the corresponding temperatures of the Air and Evaporation by means of Glaisher's Hygrometrical Tables. The mean difference between the Air and Deep Point Temperatures (Column 10) is the difference between the numbers in Columns 6 and 9, and the Greatest and Least Differences (Columns 11 and 12) are deduced from the 24 hourly photographic measures of the Dry-bulb and Wet-bulb Thermometers. The result on December 29 for Evaporation Femperature, depends partly on values inferred from eye-observations, on account of accidental loss of photographic register.

The values given in Columns 3, 4, 5, 14, and 15 are derived from eye-readings of self-registering thermometers,

No observations of the temperature of the water of the Thames were made during this month,

The mean reading of the Baremeter for the month was 30" 139, being 0" 348 higher than the average for the 20 years, 1854-1873.

Templeature of the Am.

FIG. 17 (R. 1974) A43. The lighest in the mouth was 53 *4 on December 7; and the range was 38° 9. The lighest in the mouth was 53 *4 lower than the average for the 38 years, 1841-1878. The mean of all the lawest daily readings in the mouth was 37 *4, being 7 *1 lower than the average for the 38 years, 1841-1878.

The mean gaily range was 10 · 6, being 1 · 3 greater than the average for the 38 years, 1841-1878.

The mean for the month was 32 15, being 8 13 lower than the average for the 20 years, 1849-1808.

The mean Temperature of Evaporation for the month was 31 '4, being 7' q lower than

the average for the 20 years, 1849-1868.

The mean Temperature of the Dew Point for the month was 28 '6, being 8 '8 lower than The mean Degree of Humidity for the month was 85.6, being 2.2 less than

The mean Elastic Force of Vapour for the month was on 157, being on 067 less than

The mean Weight of Vapour in a Cubic Foot of Air for the month was 1st 9, being out 7 less than

The mean Weight of a Cubic Foot of Air for the month was 568 grains, being 17 grains greater than

The mean amount of Cloud for the month (a clear sky being represented by o and an overcast sky by 10) was 7.6.

The mean proportion of Sunshine for the month (constant sunshine being represented by 1) was 0112. The maximum daily amount of Sunshine was 5 6 hours on December 6. The highest reading of the Solar Radiation Thermometer was 83 2 on December 29; and the lowest reading of the Terrestrial Radiation Thermometer was 13 7 on December 7.

The mean daily distribution of Ozone was, for the 12 hours ending 9 n.m., 0.9; for the 6 hours ending 3 p.m., 0.2; and for the 6 hours ending 9 p.m., 0.0.

The Proportions of Wind referred to the cardinal points were N. 6, E. 7, S. 8, and W. 7. Three days were calm.

The Greatest Pressure of the Wind in the month was observe on the square foot on December 30. The mean daily Horizontal Movement of the Air for the month was 230 miles; the greatest daily value was 705 miles on December 30; and the least daily value 53 miles on December 25.

Rain fell on 10 days in the month, amounting to on 652, as measured in the simple cylinder gauge partly sunk below the ground; being 1 in 135 less than the average fall for the 38 years, 1841-1878.

Highest and Lowest Readings of the Barometer, reduced to 32° Fahrenheit, as extracted from the Photographic Records.

The readings in the above table are accurate, but the times are occasionally liable to uncertainty, as the barometer will sometimes remain at its extreme reading without sensible charge for a considerable interval of time. In such cases the time given is the middle of the stationary period, the symbol: denoting that the reading has been sensibly the same through a period of more than one hour. The readings from January 1, 2th.om, and that at February 3, ob. om, or taken from the eye-observations, on account of temporary interruption of the photographic registration.

Absolute Maxima and Minima Readings of the Barometer for each Month in the Year 1879. [Extracted from the preceding Table.]

1879,	Readings of t	he Barometer.	Range of Reading

The hours are reckoned from apparent noon.

Bright-982.8 clards. 8471.2

The total registered duration of sunshine during the year was 982.8 hours; the corresponding aggregate period during which the Sun was above the horizon was 4454.0 hours; the mean proportion for the year (constant sunshine =1) was therefore 0.221.

(I.)—Reading of a Thermometer whose bulb is sunk to the depth of 25.6 feet (24 French feet) below the surface of the soil, at Noon on every Day of the Year.

The sign + implies that the change in the direction of the wind has taken place in the order N., E., S., W., N., &e., or in derect motion; the sign + implies that the change has taken place in the order N., W., S., E., N., &e., or in retrograde motion.

The times of shifts of the recording pencil, as given above, refer to the shifts made by hand, when, by the turning of the vane, the trace tends to travel or

has travelled out of range.

The sign + implies that the change in the direction of the wind has taken place in the order N., E., S., W., N., &c., or in direct motion; the sign - implies that the change has taken place in the order N., W., S., E., N., &c., or in retrograde motion.

The times of shifts of the recording pencil, as given above, refer to the shifts made by hand, when, by the turning of the vane, the trace tends to travel or has travelled ont of range.

The whole excess of direct motion for the year was 11160°.

The revolution-counter which is attached to the vertical spindle of the vane, whose readings increase with change of direction of the wind in direct motion, and decrease with change of direction in retrograde motion, gave the following readings:—

The heights of the receiving surfaces are as follows:

Above the M		evel o	f the Sea.	Above the Ft.	Ground. In.
The Two Gauges at Osler's Anemometer	205	6		50	8
Gauge on the Roof of the Octagon Room	193	2		38	4
Gauge on the Roof of the Magnetic Observatory	176	7		21	9
Gauge on the Roof of the Photographic Thermometer Shed	164	10		10	0
Crosley's Gauge	156	6		1	8
The Two Gauges partly sunk in the Ground	155	3		0	5
Above	Leve Ft.		ater.	Above Ft.	Deck. In.
Gauge on the "Royalist" Police Ship, moored in Blackwall Reach \until October 19, and afterwards in the West India Dock	17	0		8	8

The gauge on the roof of the Magnetic Observatory has been substituted for that formerly placed on the roof of the Library, which was in some degree overshadowed by the dome of the Great Equatoreal. The elevation of the new gauge is a few inches less than that of the old gauge.

During the months of November and December the two Osler gauges were greatly overshadowed by a scaffold erected round the vane of Osler's Anemometer during alterations and repairs of the wind-pressure apparatus. The results for both gauges are probably in each month too small.

The Police Ship "Royalist" was removed from Blackwall Reach into the West India Dock on October 19 for repair, and remained in dock until the end of the year. The exposure of the gauge in the latter position was not quite so good as in the river.

ROYAL OBSERVATORY, GREENWICH.

August 7 and 8. Sky cloudy. August 9. The sky was generally cloudy throughout. August 10. Generally cloudy; at midnight the sky became overcast.

No, for Refer- ence.	Path of Meteor through the Stars.
I	From direction of a Orionis disappeared at a point about 35° vertically below the Pleiades.
2	From near 3 Ursæ Majoris passed about 3° to right of α Draconis.
3	From slightly below γ Orionis, passed across ε Orionis, and disappeared a little above κ Orionis.
4	Appeared about 2 above and a little to right of z Lyra, passed exactly over \$Lyra, and disappeared about 5° to left of z Aquila
5	Appeared near γ Boötis and disappeared a little above Arcturus.
6 7 8 9	Shot from λ Andromeda: towards γ Cassiopeiae. From direction of β Cassiopeiae passed about 3° to left of ι and β Cephei. Appeared about 10° to left of Polaris and moved towards α Ursa: Majoris. Appeared about 5° below α Cassiopeiae, moved towards β Pegasi, and disappeared about half-way between these two stars. Meter Shot from a point a little to right of δ Ursa: Majoris and disappeared near θ Ursa: Majoris.
11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 30 31 31 31 31 31 31 31 31 31 31 31 31 31	Appeared near α Pegasi and disappeared a little above α Aquarii. From about 2° above and a little to right of α Lyræ passed nearly midway between δ and β Lyræ. Shot from a little to right of α Ophiuchi and disappeared a little above η Ophiuchi. Appeared a little below Polaris and disappeared a little above α Ursæ Majoris. Appeared about 2° below Polaris and disappeared near β Ursæ Minoris. Shot from θ Cephei to a little below τ Draconis. Appeared near β Andromeda, shot across δ Andromedæ, and disappeared a few degrees below α Andromedæ. Moved from α Aquilar towards η Aquilar. Appeared near α Coronæ and disappeared a short distance below ε Boötis. Shot from a point about 5° to right of α Andromedæ and disappeared near γ Pegasi. From β A. C. 1448 (Camelopardalus) to B. A. C. 2722 (Camelopardalus). From ε Persei towards Capella. From about midway between Capella and ε Persei; fell perpendicularly. Appeared near α Persei and disappeared near Capella. Shot from about midway between β Andromedæ and Saturn towards Saturn. Appeared at a point about το from γ Cephei and shot across γ and β Cephei. Appeared a little above Polaris and disappeared about το below Polaris. Moved from γ Cassiopeiæ towards Polaris. Moved from Polaris towards β Ursæ Minoris. Appeared near β Pegasi and disappeared near ε Pegasi. From Capella towards β Aurigæ. Moved from about 2° below the Moon towards Mars (observed through cloud). From near ε Cygni towards ν Cygni, disappeared behind a cloud. Passed through points about 5° above and το το right of Saturn (observed between clouds). Shot from near β Persei across α Persei. From ε Aurigæ moved perpendicularly downwards.
37 38 39 40 41 42 43 44 45 46 47 48 49 50 50 50 50 50 50 50 50 50 50 50 50 50	Appeared near z Trianguli and passed across γ Piscium towards Saturn. From near λ Draconis passed between γ and δ Ursa Majoris. From γ Ursa Majoris passed about φ to right of χ Ursa Majoris. Appeared near δ Persei, disappeared near β Persei. From a little to right of β Boötis disappeared a little to left of λ Boötis. From a little to right of β Boötis disappeared a little to left of λ Boötis. From a Boötis disappeared about z to left of ε Boötis. From β Boötis disappeared about z to left of ε Boötis. From between γ and β Pegasi moved towards ε Pegasi. From direction of β Pegasi passed across ε Pegasi. From γ Cygni towards β Cygni. From about z above and a little to left of γ Delphini, disappeared near β Aquilæ. From direction of π Trianguli passed (at center of path) about 5° above Saturn. From 2 Aquilæ to near λ Aquilæ. From a point near γ Piscium to Jupiter. Shot from γ Ursæ Mimoris to γ Draconis. From direction of γ Pegasi passed midway between β and γ Pegasi.

o, for efer- nce.	Path of Meteor through the Stars.
ı	From direction of α Pegasi passed across ϵ Pegasi.
2	From direction of a point midway between α Andromeda and γ Pegasi to a point 5° to right of Saturn.
3	From near γ Pegasi disappeared about 5 below α Pegasi.
5	From a point about 5 to left of Capella shot across β Aurigæ. From between γ and ε Capricorni towards ζ Capricorni.
6	Passed across: Piseium, moving from direction of 7 Pegasi.
7	Passed across \(\psi \) Aquarii to \(\delta \) Aquarii.
8	Appeared near γ Persei (very little motion). Appeared near γ Cassiopeiæ, moving towards 46 Cassiopeiæ (very little motion).
9	From σ Cassiopeia: passed between λ and κ Andromedia.
11	From direction of ζ Cygni passed a few degrees above α Delphini and across β Aquibe.
12	Shot across c Cassiopeia towards 3 Cephei.
13 14	From direction of Polaris disappeared between κ and λ Draconis. Passed nearly midway between α and β Cephei and θ and γ Cephei.
15	Moved on path parallel to line joining β and ϵ Cassiopeiæ and 5° above those stars.
16	Directed from β Andromedic, passed midway between α Andromedic and γ Pegasi.
17	Appeared about 3- above and a little to left of Mars and disappeared about 6° below that planet. From direction of ϵ Arietis passed midway between α Arietis and Mars.
19	From θ Piscium passed between λ and κ Piscium.
20	From a point between γ and ζ Aquilæ passed midway between δ Aquilæ and θ Serpentis.
21	From direction of γ Pegasi disappeared nearly at Jupiter.
22 23	From near ζ Persei disappeared a little to left and about 2 below the Pleiades. From a point about midway between γ and α Pegasi towards Jupiter.
24	From about midway between γ and α Pegasi fell perpendicularly.
25	From about 5 below γ Andromedæ disappeared near β Andromedæ.
26	From about 5 to left of Capella towards β Auriga.
27 28	From near Capella towards β Aurigæ. From direction of α Andromedæ passed 3° above α and ζ Pegasi.
29	From about 2^{ε} to left of ξ Andromedæ to near β Andromedæ.
30	From direction of 3 Cassiopeiæ disappeared between 8 and \(\lambda\) Andromedæ.
31	From a point a few degrees from α Andromedae passed across α Pegasi and a few degrees beyond. Passed about 3° to right of the Pleiades, moving from direction of β Persei.
33	From a point about 10° to right of the Pleiades and disappeared about 20° below and 5° to left of Mars.
34	Passed midway between 3 Persei and δ Trianguli, moving from direction of γ Persei.
35	From 3 Persei moved across e Arietis and disappeared about 10° above Mars.
36 37	Shot from 5 ₄ Andromedæ and disappeared about 3 [*] to right of β Andromedæ. Passed across α Camelopardali, moving from direction of γ Persei.
38	From 3 Andromedæ moved across ϕ Andromedæ towards ϵ Cassiopeiæ.
39	From near β Pegasi towards a point between γ Pegasi and α Andromedæ.
40	From between β and γ Pegasi towards γ Delphini. From α Arietis towards Saturn.
42	Appeared near γ Pegasi and disappeared near Jupiter.
43	From Capella to near θ Auriga.
44	From direction of 7 Andromeda to a point about midway between 3 Andromeda and 3 Trianguli. From about 8 below and 2° to left of Saturn to near 7 Ceti.
41 42 43 44 45 46 47 48	Passed across (Ceti, moving from direction of Saturn).
÷7	From b Ursæ Minoris disappeared about 5 below Polaris.
48	From direction of 3 Pegasi passed across \(\epsilon\) Pegasi and disappeared a few degrees beyond.
19 50	Shot from ϵ Arietis parallel to a line joining α and β Arietis. From Jupiter towards δ Capricorni.
51	Passed midway between ϵ Pegasi and β Aquilæ and about 5° to left of θ Aquilæ.
52	Passed across ψ Aquarii, moving from direction of a point midway between α and γ Pegasi.
53	From α Pegasi passed across θ Pegasi. Passed across φ and γ Lyræ.
54 55	From a point about 5 to right of α Lyrae shot across π and ζ Herculis.
56	From & Lyrae to z Herculis.
57	From α Arietis disappeared about 3° above β and γ Arietis. From κ Lyra to near ν Herculis.
58 5g	Appeared near 2 Trianguli and disappeared near a Trianguli.
60	Passed between J. Aquarii and Jupiter and slightly to right of 6 Aquarn.
61	From near γ Persei moved in direction of a point between 51 and γ Andromedae. Moved from a point about 5° above Jupiter and disappeared near a point between 3 Aquarii and 3 Capricorni.
62 63	Moved from a point about β above Jupiter and disappeared near a point between β Aquarii and δ Capricorni. Shot from θ Pegasi towards β Aquarii.

Vo. for Refer- ence.	Path of Meteor through the Stars.
1	Shot from η Draconis and disappeared about 4^- below θ Draconis.
2	Passed across Mars, moving towards 7 Ceti.
3 4	Appeared a few degrees to left of Capella and shot across β Auriga. Moved on a path parallel to ε and ζ Persci and about 2° to left.
5	Passed across Saturn towards η Ceti.
6	From about 8° below Saturn disappeared midway between η and θ Ceti.
7 8	Moving from direction of α Piscium passed πeross γ and α Ceti. Passed across γ Aquarii, moving from direction of γ Pegasi.
9	Shot from 8 Herculis and disappeared about 4° above a Herculis.
10	From β Ursa: Minoris towards: Draconis.
11	Appeared near Polaris and disappeared near β Ursa Minoris. From direction of β Arietis passed midway between θ and η Ceti.
13	From 3 Trianguli across a Arietis.
14	From a point about 10° to right of 7 Pegasi moved on a path parallel to line joining e Pegasi and 3 Aquarii.
15 16	Moved parallel to a line joining γ and β Cygni and about 3° to right. From β Pegasi across μ Pegasi towards θ Pegasi.
17	From β Pegasi across α Pegasi.
18	From direction of α Cassiopeiæ passed across α Andromedæ.
19	Passed between α and β Cassiopeiæ to α Camelopardali. From a point about 5° below α Aquilæ moved on line of prolongation of line joining α Delphini and α Aquilæ.
21	Passed across § Cygni towards a Aquilæ.
22	From α Cygni passed between γ and δ Cygni.
23	From α Andromedæ passed midway between α and γ Pegasi. Passed midway between β Cygni and γ Lyræ.
25	Passed about 2° to left of \(\beta \) Cygni and about 2° to right of \(\zeta \) Aquilæ.
26	From a Cygni disappeared about 5° below & Cygni.
27 28	Passed across ξ and ν Draconis and some degrees beyond. Passed across ι to α Cephei.
20	From a point about 10° to right of Saturn moved towards β Ceti.
30	From direction of a Camelopardali fell nearly perpendicularly, passing a few degrees to the right of a Ursæ Majoris.
31	Appeared near \(\xi\) Cephei and disappeared near \(\delta\) Draconis.
32 33	Passed across ζ Cygni towards α Delphini. Moved across ζ Cygni to a point about 10° to right of α Delphini.
34	From a point a few degrees above β Draconis passed midway between β and γ Draconis.
35 36	From α Cygni passed midway between γ and ξ Draconis. From direction of γ Pegasi towards γ Aquarii.
37	From a point a few degrees to left of 2 Pegasi passed between z and z Pegasi.
38	From 7 Draconis to a point about 2 below a Lyra.
39 40	From direction of α Cassiopeiae across α Cephel. From δ Cygni passed about 3° to left of α Lyrae.
41	From direction of a point midway between \(\delta\) and \(\epsilon\) Ursæ Majoris fell at right angles to a line joining those stars.
42	Appeared about 5° above and 5° to left of ϵ Ursa Majoris and fell perpendicularly.
43	Passed a few degrees to left of α Ursæ Majoris and across γ Ursæ Majoris. From near Polaris fell towards β Ursæ Minoris.
44 45	From Polaris towards 2 Cepter.
46	From between Polaris and β Ursæ Minoris moved in direction of α Ursæ Majoris.
47	From direction of a point a few degrees above γ Andromeda to a point about $^{+\circ}$ to right of δ Andromeda.
48	From near ϵ Cassiopeiæ towards π Cassiopeiæ.
49	From near a Lyra towards 3 Lyra.
50 51	From δ towards β Herculis. Appeared near β Bootis and disappeared near ϵ Boötis.
52	From 3 Pegasi towards a Pegasi,
53	Appeared near ε Ursa Majoris, passed across ζ Ursa Majoris, and disappeared a little above η Ursa Majoris.
54 55	Appeared near α Corona and disappeared near ϵ Boötis. From α Ursa Majoris to β Ursa Majoris,
56	From a point about midway between Arcturus and ϵ Boötis towards ζ Boötis.
57	From direction of z Ursae Majoris towards Arcturus.
58	From a point between α Ophiuchi and δ Herculis, moving from direction of α Lyrae.
59 60	From a point 10° to right of γ Aquilae across ζ Aquilae. From δ Ursae Majoris to α Canum Venaticorum.
61	Passed between γ and α Aquille and across δ Aquille.
62	Appeared near α Aquila, passed across γ Aquila, and disappeared near β Sagitta.

August 12. Sky partially cloudy.

August 13. Cloudy throughout, with the exception of a few breaks about midnight.

No. for Refer- ence.	Path of Meteor through the Stars.
1 2 3 4 5 6 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 27 25 26 27 28 33 34 35 35 35	From a point 5 to beft of η Urse Majoris fell downwards. From a little above ε Bootis towards Arcturus. From a little above ε Bootis towards Arcturus. From η Aquilac to a point midway between ε and ζ Aquilac. Moved on path parallel to a line joining z and β Cygni, but about γ° to right of those stars, From direction of Polaris shot across β Urse Minoris. From direction of Polaris shot across β Urse Minoris. Appeared near β Cassiopeiac, passed about 2° to right of γ Cassiopeiæ, and disappeared near ε Cassiopeiæ. Appeared near β Cassiopeiac passed between β and γ Andromedae. Appeared near Polaris and disappeared near β Urse Minoris. From alrection of α Arieits passed between β and γ Andromedae. Appeared near Polaris and disappeared near β Urse Minoris. From a Persei towards Capella. From a point midway between γ Urse Majoris and β Boötis downwards. From β Urse Minoris towards α Draconis. From β Urse Minoris towards α Draconis. From Saturn towards Mars (stars not visible). Appeared near β Persei and disappeared near α Andromedae. From α Urse Majoris towards γ Urse Majoris. From β Persei towards Capella. Appeared near α Cygni and disappeared near ε Cygni. From α Capella to near β Tauri. Appeared near β Persei and disappeared near α Persei. Appeared near β Tauri. Appeared near β Tauri. Appeared near β Cassiopeiæ and disappeared near α Persei. Appeared near β Cassiopeiæ and disappeared near γ Cassiopeiæ. From α Cephei towards β Cephei. Appeared near β Auromeda and disappeared near β Herculis. From α Cephei towards β Cephei. Appeared near β Auromeda and moved towards α Trianguli. From α Lyra towards μ Herculis passed about β Herculis. From α Lyra towards μ Herculis passed across γ Herculis towards α Trianguli. From α Lyra towards μ Herculis passed about β Urse Minoris and disappeared near α Draconis. From δ Urse Minoris and disappeared near α Draconis. From δ Urse Minoris and disappeared near α Draconis. From δ Urse Minoris and disappeared near α Draconis.
36 37	From near Polaris to S Ursæ Minoris. Appeared near Capella and disappeared near S Aurigæ.
38	Shot from ζ Aquilæ at right angles to line joining γ and ζ Aquilæ towards horizon.
39	Appeared near Polaris, travelled towards α Persei.
40	From a little to right of ϵ Cassiopeia towards γ Andromedæ.
41	Passed between κ and λ Draconis towards ϵ Ursa Majoris.
42 43	From direction of π Herculis towards δ Herculis. From ϵ Cygni disappeared about 2° to right of ϵ Cygni.
44	Passed between α and δ Persei towards a point about 10 below Polaris. Mr. A. Pead describes the path as "from α Persei [through a point between α and β Camelopardali."
45 46 47 48 49 50 51	From α Ursæ Majoris towards γ Ursæ Majoris, Shot from Capella towards β Aurigæ, Appeared near ϵ Ursæ Majoris and disappeared near η Ursæ Majoris. From near γ Ursæ Minoris towards ϵ Draconis, Appeared a little below Polaris and disappeared near η Draconis, From near ϵ Pegasi towards α Pegasi, Appeared near Polaris and disappeared a little above α Ursæ Majoris,
52 53 54 55	From near 3 Cassiopeia: towards a point 2° to right of 3 Draconis. From direction of a point about 10° above Polaris passed across 3 Draconis. From near 2 Cephei towards 2 Cephei. From near 2 Cygni towards 7 Cygni.

o. for lefer- ence.	Path of Meteor through the Stars.
ı	From direction of γ Piscium, appeared at a point nearly midway between α Arietis and γ Ceti.
2	From near λ Arietis passed across α Arietis.
3 4 5 6	Appeared about 5- below γ Cassiopeia, moved towards Polaris. Appeared near β Persei and disappeared near γ Persei. From near α Cassiopeia towards β Cassiopeiæ. From Aldebaran towards β Persei.
7 8 9	Passed midway between Capella and α Persei and at right angles to line joining Capella and β Persei. Passed about 1° or 2° to left of α Ursæ Majoris and about 4° to left of β Ursæ Majoris. From a point about 5° to left of α Persei moved towards λ Persei. From γ Andromedæ towards α Arietis.
1 1	From direction of α Ceti passed about 10° below Saturn. From near α Cassiopeiæ passed across β Cassiopeiæ.
13 14 15	From near α Cassiopeiæ passed about 2° above γ Cassiopeiæ. From a point nearly midway between ζ and ϵ Cephei towards α Cephei. From about 5° above α Andromedæ towards β Pegasi.
16	Appeared near the Pleiades and travelled towards β Auriga.
7	From direction of Mars passed across γ and β Trianguli.
8	From near 3 Ursa Minoris towards α Ursa Majoris. Dropped perpendicularly from Mars (communicated by the Astronomer Royal).
20 21 22 23 24 25 26	Shot from γ Geminorum and disappeared near α Canis Minoris. From direction of β Canis Majoris towards γ Geminorum. Appeared slightly below α Orionis and disappeared a little above α Orionis. Shot from Aldebaran towards α Ceti. Appeared near α Ursæ Majoris and disappeared near α Ursæ Majoris and disappeared near α Ursæ Majoris towards β Persei. Shot from a little below α Ursæ Majoris towards a little above α Ursæ Majoris. From β Andromedæ towards α Andromedæ. From β to α Trianguli.
9	Passed from about midway between α and γ Orionis towards γ Eridani (all visible together).
32 33 34 35 36 37 38 39 40	From nearly midway between Capella and 3 Aurigæ disappeared a little beyond δ Aurigæ. From near α Draconis passed about 5° above ι Draconis. From about 3° below α Draconis passed nearly over η Draconis. From direction of 3 Orionis passed a little below ε Leporis. From Piazzi, Hour V., No. 335, passed between 42 and 43 Camelopardali. From Procyon towards β Canis Minoris. From near ι Ursæ Majoris towards α Ursæ Majoris. From direction of ζ Orionis passed close to ε Leporis. From near κ Orionis disappeared a little above γ Pegasi.
11 12 13 14 15	From near Mars towards γ Pegasi, From about χ' to left of κ Orionis disappeared near β Canis Majoris. From β Eridani towards a point about β'' below γ Eridani. From γ Eridani towards a point about γ below γ Eridani. From γ Geminorum passed across κ Geminorum. From a little above α Orionis disappeared a little beyond γ Geminorum.
.6 .7 .8	From Aldebaran towards & Tauri. From Algelin direction of z Lyneis towards z Urso Majoris. From Rigel in direction of 53 Eridani. Passed across y and z Cassiopcia.
1 2	Passed across γ and z Cassopeae. From a point a few degrees above Aldebaran towards λ Tauri. Passed about z° above z Ceti and across γ Ceti.

Month and I 1879.	Day.	Greenwich Mean Solar Time.	Observer.	Apparent Size of Meteor in Star-Magnitudes.	Colour of Meteor.	Duration of Meteor in Seconds of Time.	Appearance and Duration of Train.	Length of Meteor's Path in Degrees.	No. for Reference.

Car ful watch was maintained for the expected Biela's counct meteors. On November 26 the sky was cloudy; on November 27 the sky was generally clear; no meteors were however, at any time seen. On November 28 the sky was partially clear, but no meteors were seen. The Moon was near to tull, so that, in any case, only very bright meteors would have been visible.

<u> </u>						
No. for Refer- ence.	Path of Meteor through the Stars.					
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21	Shot across \(\lambda\) Ursa Majoris in direction of \(\alpha\) Lyncis. Appeared near Procyon, travelled towards \(\epsilon\) Hydra (slightly curved path). From direction of Regulus disappeared at a point about \(\beta\) below Sirius. From a point about \(\beta^2\) below Procyon towards \(\epsilon\) Orionis. From a point between \(\epsilon\) and \(\geta\) Leonis towards \(\epsilon\) Hydra. From \(\beta\) conict through a point a few degrees below Procyon. From \(\beta\) Canici through a point a few degrees below Procyon and \(\beta\) Canis Minoris. From \(\beta\) Canis Minoris towards \(\beta\) Caneri. Shot between \(\beta\) and \(\geta\) Ursa Majoris from direction of \(\lambda\) Ursa Majoris. From \(\delta\) drived Majoris across \(\geta\) Ursa Majoris. From \(\delta\) Ursa Majoris across \(\geta\) Ursa Majoris. From \(\beta\) Ursa Majoris across \(\geta\) Delow \(\alpha\) Ursa Majoris. From \(\geta\) Cassiopeia across \(\lambda\) Andromeda. From a point 10° above \(\alpha\) Canim Venaticorum towards \(\lambda\) Boötis. From direction of \(\alpha\) Lyncis to \(\beta\) Ursa Majoris. From Regulus towards horizon. From \(\geta\) Pulylac towards Sirius. From direction of \(\alpha\) Doint about midway between \(\zeta\) and \(\geta\) Ursa Majoris across \(\ella\) Draconis. From direction of \(\alpha\) Doint about midway between \(\zeta\) and \(\geta\) Ursa Majoris across \(\ella\) Draconis. From a point 10° to right of \(\alpha\) Leonis.					
22 23 24 25 26 27 28 29 30	From direction of Aldebaran across δ Persei. From direction of η Ursa Majoris disappeared near β Draconis. From direction of β Anriga across η Geminorum. From η Ursa Majoris across κ Boötis, From λ Ursa Majoris across μ Ursa Majoris, From direction of β and η Ursa Majoris downwards. From near θ Leonis moved towards Arcturus (Meteor burst). Appeared near λ Ursa Majoris, shot across μ Ursa Majoris. From Polaris towards β Cassiopeia.					
31	Moved from Mars towards the Pleiades.					
32 33 34	From 3 Geminorum towards 3 Tauri. Shot from γ Geminorum, passed about midway between α and γ Orionis, and disappeared near γ Eridani. From near Capella towards γ Andromedæ.					
35 36	From direction of γ Orionis moved towards ν Eridani. From direction of a point a few degrees above Castor moved towards θ Ursæ Majoris.					
37 38 39 40 41 42	Appeared about 2° above β Cassiopeiæ and passed upwards parallel to line joining β and ϵ Cassiopeiæ. From near β Aurigæ towards a point about 5° below Polaris. From near β Cassiopeiæ towards π Pegasi. From about 2° to left of Mars passed about 2° to right of γ Ceti. From near α Cassiopeiæ towards β Pegasi. From near γ Persei in direction of α Arietis.
